Explanation of the changes in the normal dulness.—The lowering of the cardiac dulness when the erect position is assumed appears to be due to an actual lowering of the heart. The occasional rise of dulness (replacing the commoner fall) may be caused by some peculiarity of the supports of the heart, whereby it is held up unusually firmly and in such a way that its upper part comes further forward in the erect position than is generally the case. The widening of the dulness is the result of a forward movement of the heart when the erect position is assumed. Its converse, the fall of the heart away from the anterior chest-wall on assuming recumbency, is well illustrated in a pair of radiograms recently published by Professor Rudolf and Dr. Cummings of Toronto.[1] So long ago as 1885 Mr. C. J. Bond of Leicester demonstrated this change in the position of the heart by means of an air tampon passed down the œsophagus.[2]

TABLE I.*—*Thirty-six Unselected Cases with Normal Hearts.*

Sex.	Years of age.	In hospital for—	Changes on rising from recumbent to erect posture in—		
			Width of dulness.	Height of dulness.†	Depth of chest.‡

Medical Societies.

MEDICO-LEGAL SOCIETY. — The sixth annual general meeting of this society was held on July 23rd, Dr. W. Wynn Westcott, Vice-President, being in the chair.—Satisfactory reports were presented by the honorary treasurer and by the honorary secretaries and the following officers were elected for the coming year:—President: Mr. Justice Walton. Vice-President: Mr. John Troutbeck. Honorary treasurer: Mr. Walter Schröder. Honorary secretaries: Dr. Stanley B. Atkinson and Mr. Digby Cotes-Preedy. Auditors: Mr. Hubert Sweeney and Dr. F. S. Toogood. The following members were elected to fill vacancies on the council: Mr. R. Henslowe Wellington, Mr. J. Howell Evans, Dr. W. H. Willcox, and Dr. C. H. Wise.—The meeting then proceeded to discuss a paper by Mr. George Pernet on the Teaching of Medical Jurisprudence in Paris and in London.—In the subsequent discussion Dr. Wynn Westcott suggested that a similar paper dealing with German practice would be a valuable contribution. His recollection and experience led him to consider that the Morgue was a wretched, miserable, and depressing place in comparison with the mortuaries attached to his coroner's courts, though he was forced to admit that the scientific work done was of an inferior quality in the London buildings. Personally he had not missed refrigerating apparatus. He regretted that students were encouraged to analyse merely "faked" toxicological solutions, since if teachers applied to coroners they could be supplied with viscera containing the real thing from poisoned bodies; further, subject to certain regulations, he would like to see medico-legal post-mortem examinations available for teachers to use in instructing their pupils. The regulations would have to prohibit the possibility of the operators being prompted by interested parties.—Mr. Troutbeck thought that the province of a medical man was the exercise of his powers of observation rather than the deduction of legal conclusions. He noted that in Paris the study of the bodies of the living was associated with the study of post-mortem results. In London the attention paid by medical men to methods of identification was slight; this was an important matter where insurance moneys were involved. He thought that a freezing chamber attached to a mortuary was not only useful for purposes of delayed identification but also as a preventive against pathological changes in decomposing viscera. Although 60 per cent. of the inquests of London were based upon post-mortem dissections nothing further was done with the valuable material. He agreed that a large practical and official school of medical jurisprudence was necessary, and he believed that it would arise from the medical rather than from the legal profession. Given the opportunity and need experts of the highest skill would result.—Mr. Henslowe Wellington stated that at the Westminster Hospital Medical School he had striven to make the study of forensic medicine more real and practical than was usual. He had arranged that medical students should be notified as to when medical men were making necropsies at the nearest mortuary and he had gained the coroner's permission for the pupils to be present; unfortunately the times which were fixed by general medical practitioners were unavoidably inconvenient to busy students. He had also, with the consent of Sir Edward Henry, Chief Commissioner of the police, taken his class to a demonstration on the methods of finger-print identification at the Criminal Investigation Department, Scotland Yard. Further, he had taken students to the Central Criminal Court to show them the methods of criminal procedure and of giving evidence. He also announced in his syllabus of lectures that students of law were admitted to his course of lectures.—Mr. Howell Evans was convinced from experience in teaching operative surgery that bodies should be frozen, notably in order to prevent the generation of volatile bodies which, by their presence, would raise an element of doubt in the toxicological examination of minute quantities of poisons. He thought that toxicological chemistry came too early as a branch of study in the medical curriculum; the anatomy of the organs likely to be affected by the poison should be known. Similarly post-mortem work should not be enforced upon students until an appreciation of clinical and pathological entities was present. He would insist on law students having a two [illegible] of medical jurisprudence.—Dr. Willcox regretted the lack of thoroughness with which toxicology and forensic medicine were considered in this country; the position was largely the result of the crowded curriculum, for students seldom studied beyond the confines of the set syllabus. Toxicology, when met in a practical case of criminal poisoning, was a very technical and difficult exercise, and no student without previous prolonged training could ever dare to pose as an expert analyst in these matters. Most lectureships on the subject in London were honorary posts and until the hard cash obstacle was removed he doubted whether even the University of London would consider the foundation of a central School of Legal Medicine. He thought that the attendance of medical students at post-mortem examinations should be more seriously imposed.—Dr. Cowburn said that there was little teaching of morbid anatomy from the medico-legal standpoint in this country; the examination of external appearances was seldom full and complete. The remedy was to institute a post-graduate diploma in forensic medicine; even then he feared that the inducements to adopt this side of the profession would be very few as there was no great demand for this class of skilled knowledge.—Mr. Pernet, in reply, said that medical men should be encouraged to keep up their knowledge of post-mortem pathology and thereby stimulate their medico-legal interest. Every medical man should at least know how to put up viscera suspected of containing poison in such a way as to aid the toxicologist. He was surprised at the low rate at which pathologists were remunerated. To sum up the whole matter, he would urge that medico-legal examinations should be conducted in a medico-legal fashion.

Reviews and Notices of Books.

Some Problems of Existence. By NORMAN PEARSON. London: Edwin Arnold. 1907. Pp. 168. Price 7*s.* 6*d.* net.

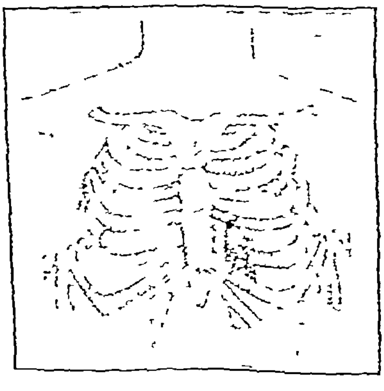
THIS book is an exposition of the author's philosophy of existence which is evidently written for the large class of thinking men with some scientific knowledge but no technical training in moral philosophy, and as such it should appeal to many of our readers. It is hardly within the province of a purely medical journal to review critically a work that is more than half theological, but it is written with such evident earnestness of purpose, and the author expresses his theses and conclusions with such lucidity and dialectical ability, that we feel justified in bringing it to our readers' notice.

Mr. Pearson starts by postulating as the working hypothesis of his theory the existence of a Deity, the personal immortality of man and a divine scheme of evolution proceeding under the sway of an inflexible order. From these premisses he elaborates a theistic scheme of religion which is boldly conceived and fearlessly expressed. There are many minds that will grant these postulates—for without the first two no religion in its full sense is possible and to deny the last is to deny modern science—but which have a too hazy and colourless conception of what they do "believe." The book offers a very strong and roseate explanation of some of the great mysteries of existence, and the man who has come under such chilling influences as the querulous wailings of the school of Nietzsche, or who still applies to the belief in predestination the awful consequences taught by Calvin's followers, may find in these hopeful pages an excellent moral corrective and tonic. The author's scheme is perhaps a little too highly polished on its speculative side, although he does not claim to be always supported by ascertained facts; in this connexion we think he would be well advised to refrain in a future edition from adducing Mr. Burke's "radiobe" experiments even as an auxiliary piece of evidence in support of his contentions, since Mr. Burke's ingenious speculations on the interpretation of the phenomena which he made known to the scientific world would seem to have been refuted by Mr. W. A. Douglas Rudge at the Royal Society. Mr. Pearson's metaphysical speculations are always alone "is indicative of the size of the heart." Such remarkable changes in such an important physical sign might have been expected to have received considerable attention; if the case in Table II., of which two records are given, had been examined, before treatment, in the recumbent posture only and, after treatment, in the erect only the marked improvement attained would have been almost wholly overlooked; on the other hand, had the case been examined at first only erect and, after treatment, only recumbent, the apparent improvement would have been much in excess of reality. Yet, extraordinary as it seems, these changes have received no adequate notice. Dr. A. Morison is one of the few who have strongly directed attention to them. His diagram of the change in dulness in a case of chorea with apical systolic murmur[5] somewhat resembles Fig. 4. That the changes have entirely escaped the observation of writers who have not referred to them I do not venture to imagine.

The Effect of Recumbency on the Heart Dulness in Cancer.

An extreme instance of the narrowing of the heart dulness on recumbency is furnished by certain cases of cancer in which ordinary emphysema can be excluded. When this marked narrowing is observed it is a sign of some value in diagnosis. It is not to be found in all cancerous cases and it is sometimes present, though rarely I think, in patients suffering from non-cancerous disease. Cases of carcinoma of some part of the alimentary canal are those in which it most commonly occurs, especially in their later stages. In cases of sarcoma it seems not to occur.[6] To be of diagnostic value the area of dulness must be greatly reduced or actually obliterated. I have ventured to lay some stress on an area only three-quarters of an inch wide, with its upper limit about the level of the fourth rib and its rightward limit about an inch to the left of the middle line of the sternum, as in Fig. 5. This small dulness is often associated with a rather characteristic pulse—very small, very soft, almost toneless—and with feeble heart sounds. The rhythm and rate of the pulse may be normal and the artery may or may not be atheromatous

FIG. 5.



Small heart dulness in the recumbent position in a case of gastric cancer.

Explanation of this sign in cancer cases.—No doubt the lessened or lost cardiac dulness of some cases of cancer is due partly to the marked wasting of the heart which is known to occur in association with carcinoma. But this cannot be the whole explanation, since one sometimes finds at the necropsy of a cancer case, in which the dulness was lost on recumbency, that the heart is of normal size. In such cases the heart is found enveloped in lung, the two lungs meeting over it in front as in emphysema. Yet sections made of the lung tissue in two such cases by my friends Mr. J. Miller and Dr. R. V. Solly of Exeter failed to show evidence of ordinary emphysema. I have provisionally ventured upon the following explanation. Just as in many cases of abdominal cancer there is a remarkable loss of elasticity in the skin of the abdomen, so possibly there may be a loss of elasticity in the tissue of the lung in virtue of which ordinary respiration gradually produces a sort of spurious emphysema, the lung edges advancing and diminishing the area of cardiac dulness. Certainly I have seen the cardiac dulness gradually grow less (in the recumbent posture) in a patient leading the quiet life of the hospital ward, who had a carcinoma of the cardiac end of the stomach verified by operation. Perhaps in the same way one might explain the peculiar tonelessness of the pulse in some of these cases as being due to diminished arterial elasticity.

The Effect of Posture on Heart Murmurs.

In 1902, when I suggested an explanation of the effect of posture on heart murmurs,[7] very little consideration appeared to have been given to the subject. Current opinion was thus summed up by Dr. Gee[8]: "Some murmurs, which are audible whilst a patient is lying down, become much less loud, or even disappear, when he sits or stands. This is especially the case with mitral and tricuspid murmurs. The reason of this occurrence is not understood." The fact that posture affects murmurs is far from new. Dr. A. E. Sansom has described carefully in Professor T. Clifford Allbutt's "System of Medicine,"[9] the changes in "hæmic" murmurs; the changes in organic murmurs referred to by Dr. Gee have long been recognised; and Dr. G. W. Balfour[10] has pointed out that the murmur of the mitral stenosis is usually loudest in the erect position. What was perhaps new four years ago was the explanation offered and the observation made that the areas over which the murmurs were audible also changed with the change of position.

In investigating these changes there are certain sources of fallacy which require to be carefully avoided. *The influence of exertion* must be eliminated by getting the patient's posture changed for him by an assistant without effort on the patient's part. The *transitory effects of the change* of posture, if any, must be given time to pass off—a few pulse-beats generally suffice. To avoid *changes due to altered positions of the auditory apparatus* a straight wooden stethoscope should be used. "*Cardio-pulmonary*" *murmurs* are to be distinguished by their dependence on respiration, their limitation to areas lying over an edge of lung, and by their failure to follow the usual directions of conduction which characterise murmurs of intracardiac origin. In dealing with the changes in the murmurs I shall confine my remarks to the murmurs most commonly met with.[11]

"*Hæmic*" *murmurs.*—1. *In the pulmonary area.*—The systolic murmur over the pulmonary artery is often greatly increased on recumbency and sometimes a murmur may be heard in that position which is inaudible when the patient is erect. The area of its audibility also is often much extended on recumbency.

2. *At the apex.*—The same holds good.

3. *In the aortic area.*—Similar changes occur here also. In a former paper I have figured an aortic and a pulmonary murmur the areas of audibility of which were separate in the erect position but fused in the recumbent.

4. *Venous hum in the neck.*—Although this is not a cardiac murmur it is desirable to refer to it here. It is often only heard in the erect position, entirely vanishing when the patient lies down.

Organic murmurs.—1. *Mitral regurgitation.*—The influence of position is often pronounced in cases with recent systolic murmurs developed in the course of chorea or acute rheumatism. These murmurs are nearly always more evident and more widely heard when the patient is lying down. Posture nearly always, too, affects in the same way the regurgitant mitral murmurs of confirmed valvular disease and of dilated auriculo-ventricular orifice.

2. *Mitral stenosis.*—Here, however, the change which *most* commonly occurs is just the reverse of the foregoing. The presystolic murmur is generally louder and more widely heard when the patient sits up. One of the loudest mitral presystolic murmurs I have met with was scarcely audible when the patient was recumbent. Fig. 3 illustrates the opposite changes of area of audibility on change of position undergone by a presystolic and a systolic murmur in a case of mitral stenosis. Both were carefully mapped out. The systolic murmur appeared to be chiefly tricuspid.

3. *Tricuspid regurgitation.*—This murmur usually follows

[11] Figures illustrating these changes were given in the paper referred to on Posture and Heart Murmurs.

We have chosen these examples because they illustrate how faithfully chemical research in this direction is serving in the interests of medicine in the hands of such giant investigators as Ostwald, Kohlrausch, van 'tHoff, and the author of the book before us. Nor do we forget those illustrious men of the past who well and truly laid the foundation of the science upon which our modern conceptions are constructed. The book is a series of lucid lectures on a difficult subject.

Treatment by Hypnotism and Suggestion, or Psycho-Therapeutics. By C. LLOYD TUCKEY, M.D. Aberd. Fifth edition, revised and enlarged. London: Baillière, Tindall, and Cox. 1907. Pp. 418. Price 10*s.* 6*d.* net.

Sir Francis R. Cruise contributes an interesting introductory chapter to this valuable work by Dr. Lloyd Tuckey, describing how, with a prejudice against hypnotism, he began to study the subject at first from books and later at the cliniques of Dr. Liébeault and Dr. Bernheim at Nancy, and of Professor J. Charcot and others at Paris. He soon became so convinced of the value of hypnotic suggestion as a therapeutic agent that he began to employ it in his private practice and now advises other physicians to do likewise. Though 18 years have elapsed since the publication of the first edition of the book under review there is still much prejudice against hypnotism in medical circles in this country. This is due probably to the fact that hypnotism is scarcely mentioned in the medical curriculum, and also because it is associated in the minds of many with quackery and foolish public demonstrations. The danger of these public exhibitions has, as Dr. Tuckey points out, been recognised abroad, and in Switzerland, Holland, and France they are prohibited by law. It is to be hoped that the Society for the Study of Psycho-Therapeutics, which has been newly formed in England with Dr. Tuckey as president, will be the means of introducing a similar law into this country.

The book is written so lucidly and pleasantly that it is difficult to lay it down. Many cases are described, both of failures and successes, and in a future edition it would be helpful to the reader if the headlines of the pages indicated their contents; at present, if the reader desires to refer to a case he has to glance through the whole book to find it. Some rearrangement of the matter would also be of advantage. Chapters VI., VIII., and IX., which deal with the scientific explanations of hypnotism, might be condensed and Chapter VII., which breaks in upon the line of argument, might be made to precede or to follow them. Dr. Tuckey's book has now grown large enough to be able to dispense with the description in Chapter X. of 31 cases of other medical practitioners, and we trust that when this chapter is abbreviated the author will omit the case of syphilitic retinitis to which we objected in our review of the fourth edition.

The question of the use of hypnotism in organic disease is discussed more fully on pp. 200 et seq. than on the page (390) mentioned in the index. The author states: "No physician will have the temerity to maintain that destroyed lung tissue can be restored, or that liver cells spoilt by cirrhosis can be replaced. But there are stages in a disease short of the dissolution of tissue in which ...... we may hope for *restitutio ad integrum.* ...... We can also afford relief by removing symptoms ...... as in incurable diseases, such as cancer."

Treatment by suggestion is to-day so widely believed in by the public that every medical man should know something about it if only to answer the questions put by his patients. The recent interest in psychical subjects and the power of mind over matter and the rise of various faith-healing sects have led to a prolific production of pseudo-scientific writings by irresponsible persons who are regarded as authorities by the laity. We therefore heartily welcome this new edition of a book on healing by suggestion which is scientific, careful, and written with the candour and adherence to fact which are characteristic of the genuine searcher after truth. We consider that this unprejudiced study of an important subject should be in the hands of every medical man.

Surgical Instruments in Greek and Roman Times. By JOHN STEWART MILNE, M.A., M.D. Aberd. Oxford: The Clarendon Press. 1907. Pp. 187 and 54 plates. Price 14*s.* net.

IT is a matter for congratulation that the first description of the surgical instruments of the ancients which has been published since the recent discoveries of new works of classical literature and the great increase in the number of specimens of such instruments themselves in museums and private collections should have been produced in our country. This work by Dr. John Stewart Milne provides a very able if not entirely complete account of almost all the known specimens of Greek and Roman surgical instruments, and gives very adequate illustrations of the uses to which they were applied by extracts from the classical medical authors, accompanied by intelligible translations of their remarks into English, a matter of no small difficulty. He also gives a commentary upon the citations themselves, and describes, so far as possible, the instruments, assisted by numerous reproductions of photographs, and the manner in which they were utilised.

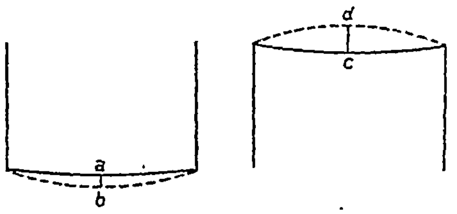
As he points out in his preface, many interesting operations described in detail in the classic authors were rendered obscure or even unintelligible because we were ignorant of the shape and action of the instruments they used. He specially instances the vaginal speculum, to which Paulus Ægineta devotes a long chapter well known to classical scholars, but it was impossible to appreciate properly his explanation of its use until specimens of the ancient instrument were found. Dr. Milne does not, however, appear to be familiar with Dr. Deneffe's treatise, "Le Speculum de la Matrice à Travers les Ages," treating of this special subject, and giving illustrations of several instruments for dilating the vagina. It is doubtful, however, whether a mirror ever formed part of the ancient apparatus, although Dr. Deniffe thinks it was so.[1] Dr. Milne does not in his illustrations show, or in his work discuss, the ancient mechanical contrivances for the reduction of deformities or the adjusting of dislocations and fractures, such as splints or pads, neither does he more than allude to the special vessels which, in antiquity, were used for containing unguents and medicaments, but to have done so would have been outside the intention of his book and may well be left for another work. He gives, however 54 excellent heliotype plates, many of them presenting from six to eight different surgical instruments. Unfortunately, the book contains no list of these plates or table of their contents, and so in doubtful cases their uses can only be ascertained by searching for the reference to the plate in the body of the book. The introduction gives a summary of the chief medical authors of classic times, commencing with the Hippocratic collection, but omitting the papyrus manuscript of the Iatrica of Menon which has been adequately edited by Diels. Special mention is made of the seventh book of Celsus, which gave a detailed account of the surgical school at Alexandria and describes the instruments used therein, many of which probably were copied from those known to the ancient Egyptian surgeons. The summary of ancient medical writers includes those of

---

[1] The fragments of a circular mirror were found together with what appears to be a surgeon's lancet, in what is believed to be the tomb of a medical man at Wroxeter.

Mitral and tricuspid regurgitant murmurs.—As regards these murmurs it should be remembered that the full intraventricular systolic pressure is not immediately attained when the ventricle begins to contract and that the murmur is loudest at its beginning, whilst the pressure is relatively low. With regard to the sounds produced at the semilunar valves the following objections have been urged: (*a*) that, as the circulation forms a system of closed tubes, gravity can produce no effect within it, ascending columns of blood balancing descending columns; (*b*) that the aorta acts as a syphon; and (*c*) that the change in the second sound on assuming the upright position is due to an increase in the blood pressure in the aorta and pulmonary artery consequent on that position.

FIG. 8.



Position 1. Position 2.

To these objections the following reply may be made: (*a*) It has been shown by Dr. Leonard E. Hill and others that gravity does act within the circulation. Table IV., prepared from observations kindly taken for me with the Riva-Rocci instrument by Mr. A. Hawkins, house physician to the Royal Devon and Exeter Hospital, shows in the majority of the cases observed a very decided effect of gravity on the blood pressure. The pressure was taken in the brachial artery in three positions—viz., (1) with the body erect (sitting) and the arms hanging at the side, elbow bent, the hand resting on the arm of the chair; (2) body erect (sitting) with the arm held extended vertically over the head by an assistant so that no exertion was made by the person under observation; and (3) body recumbent, with the arm extended by the side. (*b*) Directly after systole the aorta and its branches are so over-distended with blood that their elastic recoil shuts the aortic valves. Under these circumstances it seems impossible to argue that just before the closure of the valves the aorta is acting as a syphon. In the pulmonary circuit gravity can act as well as in the systemic circulation for the same reason—viz., that the vessel walls are not rigid and are under the influence of atmospheric pressure. When the body is upright it is clear that the blood in the pulmonary artery and the lungs above its level is above the level of the semilunar valves; when the body is recumbent the whole pulmonary circulation is clearly below the level of these valves. All that is necessary to account for the change in the sounds is that a very small weight of the pulmonary blood, just enough to close and slightly stretch the valves, shall be allowed to rest on them by the want of rigidity of the pulmonary vessels. (*c*) Table IV. seems to show that the third objection rests on a mistake. The cases given are too few to make a more general assertion. At all events, this third objection is quite unsupported by proof.

The Effect of Posture on the Accentuated Pulmonary Second Sound.

The accentuated pulmonary second sound, as heard in the second left interspace close to the sternum, is more marked—often much more marked—in the recumbent posture than it is in the erect. This is doubtless due to the coincident decrease of chest-depth bringing the chest wall so much closer to the pulmonary valve. That it does is in some cases proved by the fact that on recumbency the shock of their closure becomes here actually palpable.

The Effect of Posture on the Reduplicated Second Sound.

The reduplicated second sound, as heard over the pulmonary artery, even in mitral stenosis, is often more markedly divided in the recumbent than in the erect position —indeed, it is sometimes only reduplicated on recumbency. It is generally supposed that the reduplication is due to asynchronous closure of the aortic and pulmonary valves. Balfour,[12] however, has pointed out that this cannot be always the case, because the reduplication of the second sound has been observed in patients in whom the aortic second sound was completely replaced by an aortic regurgitant murmur. Guttmann has suggested that the reduplication may be sometimes due to asynchronous closure of the cusps of one set of semilunar valves, but I cannot discover that he has offered any proof of this. My observations lead me to think that the mode of production suggested by Guttmann is the usual one and that the pulmonary cusps are usually those whose want of synchronism in closure divides the sound. My reasons for this conclusion are as follows. In the recumbent posture: (1) the reduplication is best heard in almost all cases directly over the pulmonary artery, not midway between the points where the second aortic and second pulmonary sounds are respectively best heard; (2) its area of audibility frequently does not include the aortic area, though it extends a considerable distance to the left of the pulmonary area; (3) the two parts of the doubled sound are often loud when the aortic sound heard directly over the aorta is weak; and (4) in two cases in which the shock of the closure of the pulmonary valves could be easily felt in the second left space close to the sternum, the shock was distinctly felt to be double, just as the sound was.

Conclusion.

To sum up briefly the foregoing, in most cases the change from the erect position to the recumbent: 1. Raises and narrows the normal cardiac dulness. 2. Makes the first heart sound duller and the second sharper, thus producing the classical "lub-dup." 3. Diminishes the antero-posterior diameter of the chest. 4. Markedly narrows the dulness of an enlarged heart. 5. Increases the loudness and area of audibility of (*a*) "hæmic murmurs" both at the base and apex; (*b*) mitral and tricuspid regurgitant murmurs; and (*c*) aortic stenotic murmurs. (Some of these murmurs may only be audible in the recumbent posture.) 6. Lessens the loudness and area of audibility of (*a*) the "venous hum" in the neck; and (*b*) the presystolic murmur of mitral stenosis. (Some of these murmurs may only be audible in the erect posture.) 7. Leaving unaffected the murmur of aortic regurgitation. 8. Increases the loudness of the accentuated pulmonary second sound. 9. Makes more marked the reduplication of the reduplicated second sound. (In some cases the reduplication is only heard in the recumbent position.) 10. Causes the partial or complete disappearance of the cardiac dulness in certain cases of cancer in their later stages. Taking all these facts into consideration, I would submit that it has been shown that no description of the cardiac physical signs can be regarded as complete which does not include a statement of the position of the patient at the time of observation.

[12] Op. cit., p. 35.

THE CULTIVATION OF QUININE IN THE CONGO.—The Congo Government has sent out a certain number of quinine trees (cinchona), chosen from the eight best kinds, to Central Africa. It is proposed to plant them in different provinces at a minimum altitude of 2400 feet above the sea. During the coming winter 2000 more shoots from the nurseries in the colonial garden at Laeken will be sent out.

containing it in a free state are scheduled as poisons. Were this the case in Great Britain a stop would be put to the sale of quack remedies containing free phosphorus, which are widely advertised in the daily press, and we presume widely bought by the public. Another drug scheduled as a poison in Ireland is sulphuric ether, which used to be commonly used in the north of Ireland with a view to obtaining rapid intoxication.

A Handbook to the Workmen's Compensation Act, 1906. By G. F. EMERY, LL.M., Barrister-at-Law. *London: Bemrose* and Sons. 1907. Pp. 102. Price 1*s.* net.—This handy exposition of the most prominent measure of the present Government will prove a useful guide to the intricacies of the Act. Many sorts of employers who have not fully mastered its clauses would do well to study them in this little book. If it served no other good purpose it would be a salutary reminder of the urgent necessity for insurance against its penalties. It is essential for practitioners in general to be familiar with its provisions, and they may here find them clearly set forth and explained as far as they may be at present.

Low's Handbook to the Charities of London. London: Eliot Boothroyd. 1907. Pp. 288. Price 1*s.* net.—The fact that this handbook has attained its seventy-second year of issue is sufficient proof of its utility. Information is given about over 1200 charitable institutions which is thoroughly trustworthy. A short historic sketch of St. Bartholomew's Hospital is included in the preface of this edition.

Police Surgeon's Emergency Guide. By C. GRAHAM GRANT, L.R.C.P. & S. Edin. London: H. K. Lewis. 1907. Pp. 77. Price 2*s.*—Mr. Grant has compiled a valuable little book, one, moreover, which not only police surgeons but other general practitioners, more especially resident medical officers in hospitals, will find most useful. His hints and experiences on the all-important questions of "Drunk or sober?" "Drunk or dying?" are interesting. We note that under the heading of Camphor Poisoning he says: "For treatment see appendix." We were unable, however, to find any further mention of camphor. Mr. Grant also has the good sense and the candour to tell his readers how and where he made mistakes, and though it is most easy to learn from our own mistakes it is only a little less easy to learn from the mistakes of others. "If," says Mr. Grant, in discussing the question of the opinion which the practitioner gives on the question of how long life has been extinct, "you are wrong, you will look a fool, and if right a wise man. The author has done both." One omission we hope to see filled up in the future editions of this book which we have no doubt will be called for, and that is the omission of syncope as a cause of death in bodies found in the water. Also on page 69, in mentioning blood stains, Mr. Grant, after giving directions for the guaiacum and peroxide of hydrogen test, says "the Prussian blue will be seen." We suppose that he means the colour so called, but Prussian blue in chemistry is a substance and not a colour, and, moreover, to our eyes the blue colour of the guaiacum test is not Prussian blue but rather the blue of perchromic acid. Possibly, however, Mr. Grant's intimate association with the police has given him a special affection for the colour in question. Everyone will remember Leech's omnibus driver addressing the policeman as "Vell, my Prooshian Blue!" But these two slight blemishes notwithstanding, we congratulate Mr. Grant upon his book.

JOURNALS AND MAGAZINES.

The Edinburgh Medical Journal.—In the July number is published an oration delivered before the Medical Society of London by Dr. G. A. Gibson on the Cause of the Heart-beat, in which he criticises the accepted view that the movements of the heart are due to the intrinsic properties of its muscular substance and argues in favour of nervous influence as the effective cause. Mr. H. Alexis Thomson writes on Differentiation of Partial from Total Transverse Lesions of the Spinal Cord, and Mr. William Guy on the Administration of Gas and Ethyl Chloride for Anæsthetic Purposes. Dr. H. Douglas Wilson deals with the Signs and Symptoms of Mucous Colitis and enumerates the many troubles arising in other parts of the body besides the intestines, such as arthritis and mental and circulatory disturbances. Mr. K. W. Monsarrat writes on Renal Sarcoma in Children and tabulates the recorded cases of the affection, which afford distinct encouragement to operate; and Dr. G. A. Gordon as the result of observations on a performer who gave an exhibition of prolonged club-swinging concludes that gentle exercise tends to raise the blood pressure but violent exertion to reduce it.

The Scottish Medical and Surgical Journal.—The July number of this journal contains a very instructive article by Mr. Charles W. Cathcart on the Use of Massage and Movement in the Treatment of Fractures. The change which has recently taken place in this branch of surgery is very remarkable and the advantages of the new methods are beyond dispute. A paper by Dr. J. S. Fraser and Dr. J. D. Comrie calls attention to peculiarities in the mode of conveyance of infection in epidemic cerebro-spinal meningitis. Here school epidemics are unknown, second cases are rare in one house, and cases introduced into scarlatinal wards do not lead to further infection. They show that meningococci haunt the naso-pharynx and are conveyed by adults to children; hence it is advisable to isolate all "contacts" and to examine their nasal and pharyngeal cavities bacteriologically, only allowing them out of quarantine when the organisms have disappeared from these parts.

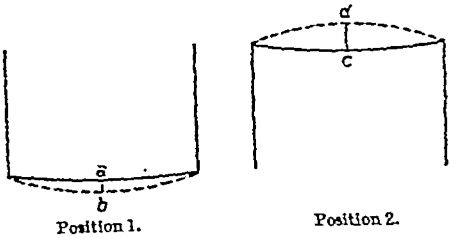
The West London Medical Journal.—The July issue of this journal opens with the Cavendish lecture, delivered by Mr. C. B. B. Keetley on the Conservative Surgery of the Abdomen, which was published in THE LANCET of June 29th, p. 1761. Mr. Richard Lake writes on the results of nasal obstruction as it affects the pharynx, the ear, the larynx, and other parts. Mr. George Pernet contributes a learned paper with an extensive bibliography on hæmorrhagic rashes, in which the complexity of the problem presented by these affections is pointed out and attention is drawn to the co-existence of bacterial infection in many of them. Mr. Leonard S. Dudgeon reports a case of poisoning by antikamnia, in which the livid blue colour of the patient's skin was remarkable.

St. Bartholomew's Hospital Journal.—The July number contains some clinical notes on pericarditis by Dr. Samuel West and a series of "Pædiatric Aphorisms" by Dr. William P. S. Branson, both of which articles are well worthy of study. Dr. J. G. Gibb records two cases of traumatic coxa vara illustrating the association of adolescent coxa vara with slight injuries, the long interval which may elapse before the development of any severe disability, and the occurrence of a stage in which the limitation of movement is far greater than that produced by the bony deformity, being caused by muscular fixation.

CARDIFF INFIRMARY.—The foundation-stone of the new out-patient department of this infirmary was laid on July 30th by Sir William T. Lewis and after the ceremony an address was given by Mr. Edmund Owen, who spoke in high terms of the good work which was being carried out in the institution. The cost of the extension is estimated at £8000, a sum which has been already subscribed. It is anticipated that the larger scheme for providing an additional pavilion will also be realised. One half of the estimated cost of £30,000 has already been promised and with the trade of the district in its present flourishing condition there ought to be no difficulty in raising the remaining amount. The latter project includes provision for 70 more beds, a new gynæcological operating-room, lifts to connect the wards on the first floor, and a clinical laboratory, museum, and new post-mortem room.

Mitral and tricuspid regurgitant murmurs.—As regards these murmurs it should be remembered that the full intraventricular systolic pressure is not immediately attained when the ventricle begins to contract and that the murmur is loudest at its beginning, whilst the pressure is relatively low. With regard to the sounds produced at the semilunar valves the following objections have been urged: (*a*) that, as the circulation forms a system of closed tubes, gravity can produce no effect within it, ascending columns of blood balancing descending columns; (*b*) that the aorta acts as a syphon; and (*c*) that the change in the second sound on assuming the upright position is due to an increase in the blood pressure in the aorta and pulmonary artery consequent on that position.

FIG. 8.



To these objections the following reply may be made: (*a*) It has been shown by Dr. Leonard E. Hill and others that gravity does act within the circulation. Table IV., prepared from observations kindly taken for me with the Riva-Rocci instrument by Mr. A. Hawkins, house physician to the Royal Devon and Exeter Hospital, shows in the majority of the cases observed a very decided effect of gravity on the blood pressure. The pressure was taken in the brachial artery in three positions—viz., (1) with the body erect (sitting) and the arms hanging at the side, elbow bent, the hand resting on the arm of the chair; (2) body erect (sitting) with the arm held extended vertically over the head by an assistant so that no exertion was made by the person under observation; and (3) body recumbent, with the arm extended by the side. (*b*) Directly after systole the aorta and its branches are so over-distended with blood that their elastic recoil shuts the aortic valves. Under these circumstances it seems impossible to argue that just before the closure of the valves the aorta is acting as a syphon. In the pulmonary circuit gravity can act as well as in the systemic circulation for the same reason—viz., that the vessel walls are not rigid and are under the influence of atmospheric pressure. When the body is upright it is clear that the blood in the pulmonary artery and the lungs above its level is above the level of the semilunar valves; when the body is recumbent the whole pulmonary circulation is clearly below the level of these valves. All that is necessary to account for the change in the sounds is that a very small weight of the pulmonary blood, just enough to close and slightly stretch the valves, shall be allowed to rest on them by the want of rigidity of the pulmonary vessels. (*c*) Table IV. seems to show that the third objection rests on a mistake. The cases given are too few to make a more general assertion. At all events, this third objection is quite unsupported by proof.

TABLE IV.—*Blood Pressure Estimations with Riva-Rocci Instrument applied over Brachial Artery on 12 Different Persons in Three Different Positions. These were kindly made for me by Mr. A. Hawkins.*

The Effect of Posture on the Accentuated Pulmonary Second Sound.

The accentuated pulmonary second sound, as heard in the second left interspace close to the sternum, is more marked—often much more marked—in the recumbent posture than it is in the erect. This is doubtless due to the coincident decrease of chest-depth bringing the chest wall so much closer to the pulmonary valve. That it does is in some cases proved by the fact that on recumbency the shock of their closure becomes here actually palpable.

The Effect of Posture on the Reduplicated Second Sound.

The reduplicated second sound, as heard over the pulmonary artery, even in mitral stenosis, is often more markedly divided in the recumbent than in the erect position—indeed, it is sometimes only reduplicated on recumbency. It is generally supposed that the reduplication is due to asynchronous closure of the aortic and pulmonary valves. Balfour,[12] however, has pointed out that this cannot be always the case, because the reduplication of the second sound has been observed in patients in whom the aortic second sound was completely replaced by an aortic regurgitant murmur. Guttmann has suggested that the reduplication may be sometimes due to asynchronous closure of the cusps of one set of semilunar valves, but I cannot discover that he has offered any proof of this. My observations lead me to think that the mode of production suggested by Guttmann is the usual one and that the pulmonary cusps are usually those whose want of synchronism in closure divides the sound. My reasons for this conclusion are as follows. In the recumbent posture: (1) the reduplication is best heard in almost all cases directly over the pulmonary artery, not midway between the points where the second aortic and second pulmonary sounds are respectively best heard; (2) its area of audibility frequently does not include the aortic area, though it extends a considerable distance to the left of the pulmonary area; (3) the two parts of the doubled sound are often loud when the aortic sound heard directly over the aorta is weak; and (4) in two cases in which the shock of the closure of the pulmonary valves could be easily felt in the second left space close to the sternum, the shock was distinctly felt to be double, just as the sound was.

Conclusion.

To sum up briefly the foregoing, in most cases the change from the erect position to the recumbent: 1. Raises and narrows the normal cardiac dulness. 2. Makes the first heart sound duller and the second sharper, thus producing the classical "lub-dup." 3. Diminishes the antero-posterior diameter of the chest. 4. Markedly narrows the dulness of an enlarged heart. 5. Increases the loudness and area of audibility of (*a*) "hæmic murmurs" both at the base and apex; (*b*) mitral and tricuspid regurgitant murmurs; and (*c*) aortic stenotic murmurs. (Some of these murmurs may only be audible in the recumbent posture.) 6. Lessens the loudness and area of audibility of (*a*) the "venous hum" in the neck; and (*b*) the presystolic murmur of mitral stenosis. (Some of these murmurs may only be audible in the erect posture.) 7. Leaving unaffected the murmur of aortic regurgitation. 8. Increases the loudness of the accentuated pulmonary second sound. 9. Makes more marked the reduplication of the reduplicated second sound. (In some cases the reduplication is only heard in the recumbent position.) 10. Causes the partial or complete disappearance of the cardiac dulness in certain cases of cancer in their later stages. Taking all these facts into consideration, I would submit that it has been shown that no description of the cardiac physical signs can be regarded as complete which does not include a statement of the position of the patient at the time of observation.

THE CULTIVATION OF QUININE IN THE CONGO.—The Congo Government has sent out a certain number of quinine trees (cinchona), chosen from the eight best kinds, to Central Africa. It is proposed to plant them in different provinces at a minimum altitude of 2400 feet above the sea. During the coming winter 2000 more shoots from the nurseries in the colonial garden at Laeken will be sent out.

The public lecture was delivered by Sir John Moore on Friday evening. He took for his subject, Weather, Climate, and Health. Practical meteorology was of great importance and he criticised the British Government for only devoting £70,000 per annum to this subject. Infantile mortality was shown to be specially connected with the rise of temperature in the summer. Tuberculosis was not closely connected with climate and Sir John Moore gave figures showing that in the western portion of Ireland there was a relatively low death-rate from tuberculous diseases, while in the urban districts of Dublin, Cork, Belfast, and Derry the rate was much higher. This was due to the fact that the old urban tenements were very unhygienic and were full of the poison of tuberculosis. Sunlight was one of the most powerful remedies against the tubercle bacillus and owing to the window tax of 100 years ago old urban tenements were very badly supplied with window space.

Under the high-sounding title of the International Golf Match an annual contest between medical golfers of different nationalities takes place at each meeting of the Association and this year the contest took place on the Exeter links, which are beautifully situated on the hills overlooking the cathedral city. The views from the course are unrivalled, but the golf was only excellent in parts, for although the competitors were enthusiastic sportsmen the strange links and the exceedingly difficult hazards played havoc with the best-intentioned shots. The match resolved itself into a fight between England and Scotland through the absence of any Irish or Welsh champions and resulted in a tie. Subjoined are the scores :—

MEDICINE.

THURSDAY, AUGUST 1ST.

Discussion on the Diagnosis of Acute Pancreatitis.

Professor W. OSLER (Oxford) in introducing the discussion referred to the work done upon the subject by various workers with whom he had been associated at the Johns Hopkins Hospital, notably Dr. Opie, Dr. Halsted, and Dr. Thayer. Within his memory there had been three stages in their knowledge regarding the pancreas; firstly, when it was regarded as a silent region of the body, only affected by cancer and such conditions as an occasional cyst; secondly, when the interesting work of Dr. R. Fitz had revealed the importance of such conditions as acute pancreatitis and pancreatic hæmorrhages and also had shown that pancreatic cysts were not uncommon; and, thirdly, the light thrown on the subject by the experimental work on acute pancreatitis and on the relation of disease of the pancreas to other conditions such as diabetes. There were two great groups of cases of acute pancreatitis, one in which there was marked swelling of the gland tissue, partly serous and partly hæmorrhagic in character, involving the whole gland or a part of it, the hæmorrhage sometimes being so extensive that it was difficult to say whether there were inflammatory changes present as well, though these could usually be recognised. In the second class of case there was suppuration going on to abscess formation or necrosis proceeding to actual gangrene. It was also not easy to say whether the hæmorrhage preceded the inflammation or was a sequel of it, but in cases of rapid death from pancreatic hæmorrhage there was an absence of fat necrosis which was so marked in pancreatitis. Three groups of causes of acute pancreatitis could be distinguished: (1) mechanical, such as from stone in the duct, rendering it vulnerable to bacterial invasion; (2) chemical irritation from substances such as bile and gastric juice which on experimental injection in animals produced acute pancreatitis; and (3) bacterial, this probably occurring only after stasis, causing the pancreatic juice to lose its bactericidal properties. A recent analysis of 105 cases had shown that in 45 the disease had been associated with gall-stones, particularly in the ampulla of Vater. Such cases with gall-stones might have recurring chills for years without developing pancreatitis, but in certain of them this occurred. In 33 out of the 105 cases there was a history of preceding gastro-intestinal symptoms, a large proportion being in alcoholics. In such cases there were probably duodenitis and catarrhal inflammation of the pancreatic duct allowing bacterial invasion. 11 of the 105 cases were associated with mumps; of these ten recovered and one proved fatal after suppuration. In the diagnosis of the condition it was well to remember that there were, clinically, two types, an acute and a subacute. The acute form presented the most acute group of abdominal symptoms with which they met. The patient was seized abruptly by agonising pain, which at once rendered him prostrate. It was paroxysmal in character, but was a most constant feature; vomiting occurred almost immediately after the pain and persisted; it consisted at first of the gastric contents and subsequently became intestinal in character, like that of acute obstruction of the small intestine. Extreme collapse quickly supervened, with coldness and lividity of the hands and feet, and a very diffuse light cyanosis over a great part of the body. Tenderness was at first diffuse, but later became more marked in the upper part of the abdomen, where some diffuse swelling might occur which was soon masked by general distension. In a large majority of the cases it was not possible to make a diagnosis, but a history of previous alcoholism in a middle-aged man with such symptoms might be suggestive. It required early and prompt operation for its treatment, since it was a very fatal malady, the patient dying collapsed at the end of two or three days. In the second group, the subacute or suppurative type of case, the onset was less acute and fulminant in character; the pain was less severe, there were fever, chill, and leucocytosis, and the gradual development of a tumour mass in the upper part of the abdomen. The examination of the fæces and the urine might help in the diagnosis; in the former there might be fragments of necrotic pancreas with a fatty character of the stools. In regard to prognosis Ebner, from a study of 96 cases, found that 90 per cent. of those not operated upon died, while 52·8 per cent. were saved by operation. The prognosis was most serious in those cases with gall-stones. The points he would suggest for discussion were the symptoms associated with acute pancreatitis, its etiology, the value of the examination of the fæces and urine, and the question of operation.

Dr. P. J. CAMMIDGE (London) had been much struck by the small proportion in which a diagnosis was made before death or operation. On examining the records of 50 recent cases he found that 12 had been regarded as perforated gastric ulcer, 12 as intestinal obstruction, four as acute peritonitis, two as appendicitis, two as cholecystitis, one as strangulated hernia, one as angina pectoris, while in 11 no diagnosis had been arrived at, and in five the diagnosis had been made and confirmed. It was therefore important to discover some aid to diagnosis. An examination of the fæces, which might be expected to afford assistance, was usually impossible owing to the constipation which was the rule; in chronic cases there was a large excess of undigested muscle fibre and of fat, especially an excess of unsaponified fat over the saponified. As far as he had been able to find out in acute cases these conditions were not present; indeed, rather the reverse might be the case. With regard to the urine he had examined it in seven cases of acute pancreatitis, in one of the subacute form of the disease, and in one case of glycosuria following upon recovery after acute pancreatitis. In four of these cases there was a considerable amount of acetone and of diacetic acid, in five a large number of calcium oxalate crystals, in four bile, and in five urobilin. He thought that the presence of urobilin was an evidence of catarrh spreading into the bile passages and pancreatic duct. Wolsey had stated that a temporary glycosuria might be seen in 10 per cent. of these cases in the first day or two. Dr. Cammidge then referred to the so-called "pancreatic reaction" described by himself in 1904 and improved in 1906. Five of his cases had been examined by the original method, in which there was a serious personal element, *with sublimate fixation, gold-tungstate toning, cyanide decolourization.*—In some of the preparations the nuclei of the epithelial cells at the growing edge of the tumour contain from one to 20 black spherical bodies varying from about 0·2 to 0·5 μ in diameter (Fig. 1). They occur singly or in pairs, less commonly in chains of three or four. Elongated forms are very occasionally to be observed. These bodies persist during the mitotic division of the cell. The chromatin and nucleoli of the epithelial cells are decolourized, as are also most of the other tissue elements throughout the preparation and therefore these special bodies may conveniently be spoken of as cyanide-fast. This character is, however, only comparative, for, by continuation of the action of the cyanide, the gold deposit can be completely removed from the tissues. In another set of preparations these spherical intranuclear bodies are only rarely to be observed, but most of the epithelial cells contain in their protoplasm, occasionally also in their nucleus, more or less numerous bodies of elongated form, appearing for the most part as short twisted and kinked threads (Fig. 4). Many of them are distinctly spiral in form. The ends are often tapered to a fine point. Many curious forms occur, which, however, need not be described here. These elongated bodies appear to have developed from the intranuclear structures just described, as transition forms can be seen and both types are cyanide-fast. They may frequently be observed in cells undergoing mitosis (Fig. 5). The cell figured contains a body which is morphologically identical with spirochæta microgyrata. It is, however, to be noted that indirect division of the cell appears often to result in the ejection of these bodies, as an aggregation of them may not infrequently be observed at the edge of a dividing cell, the protoplasm of which is devoid of them. As a rule, however, the dividing cells contain these bodies. In some portions of the tumour there may be observed, lying in the connective-tissue spaces, numerous delicate bodies of irregular outline from about 2 to 8 μ in length (Fig. 8). They constantly show a small rounded black body in their interior and thus they have the aspect of nucleated structures. They are to all appearance delicate amœboid bodies. As a rule, they are extracellular, but they have occasionally been seen within the protoplasm of an epithelial cell. They appear to arise by a simple transition from the thread-like bodies just described. This tumour is infiltrated with wandering polymorphonuclear leucocytes which show the most remarkable evidences of chemiotactic attraction towards all forms of these peculiar bodies. They push their way between the epithelial cells and when in this situation they almost constantly show cyanide-fast bodies in their interior (Fig. 6). Quite commonly these leucocytes can be seen to be lying in part within the protoplasm of an epithelial cell; some have been observed to be inclosed by the protoplasm and one has even been found within a nucleus. The phagocytes among the connective tissues contain the same bodies in various stages of disintegration and represented ultimately by only a mass of fine granules of a reddish-brown colour.

Discussion on the Diagnosis of Acute Pancreatitis.

Professor W. OSLER (Oxford) in introducing the discussion referred to the work done upon the subject by various workers with whom he had been associated at the Johns Hopkins Hospital, notably Dr. Opie, Dr. Halsted, and Dr. Thayer. Within his memory there had been three stages in their knowledge regarding the pancreas: firstly, when it was regarded as a silent region of the body, only affected by cancer and such conditions as an occasional cyst; secondly, when the interesting work of Dr. R. Fitz had revealed the importance of such conditions as acute pancreatitis and pancreatic hæmorrhages and also had shown that pancreatic cysts were not uncommon; and, thirdly, the light thrown on the subject by the experimental work on acute pancreatitis and on the relation of disease of the pancreas to other conditions such as diabetes. There were two great groups of cases of acute pancreatitis, one in which there was marked swelling of the gland tissue, partly serous and partly hæmorrhagic in character, involving the whole gland or a part of it, the hæmorrhage sometimes being so extensive that it was difficult to say whether there were inflammatory changes present as well, though these could usually be recognised. In the second class of case there was suppuration going on to abscess formation or necrosis proceeding to actual gangrene. It was also not easy to say whether the hæmorrhage preceded the inflammation or was a sequel of it, but in cases of rapid death from pancreatic hæmorrhage there was an absence of fat necrosis which was so marked in pancreatitis. Three groups of causes of acute pancreatitis could be distinguished: (1) mechanical, such as from stone in the duct, rendering it vulnerable to bacterial invasion; (2) chemical irritation, from substances such as bile and gastric juice which on experimental injection in animals produced acute pancreatitis; and (3) bacterial, this probably occurring only after stasis, causing the pancreatic juice to lose its bactericidal properties. A recent analysis of 105 cases had shown that in 45 the disease had been associated with gall-stones, particularly in the ampulla of Vater. Such cases with gall-stones might have recurring chills for years without developing pancreatitis, but in certain of them this occurred. In 32 out of the 105 cases there was a history of preceding gastro-intestinal symptoms, a large proportion being in alcoholics. In such cases there were probably duodenitis and catarrhal inflammation of the pancreatic duct allowing bacterial invasion. 11 of the 105 cases were associated with mumps; of these ten recovered and one proved fatal after suppuration. In the diagnosis of the condition it was well to remember that there were clinically two types, an acute and a subacute. The acute form presented the most acute group of abdominal symptoms with which they met. The patient was seized abruptly by agonising pain, which at once rendered him prostrate. It was paroxysmal in character, but was a most constant feature; vomiting occurred almost immediately after the pain and persisted; it consisted at first of the gastric contents and subsequently became intestinal in character, like that of acute obstruction of the small intestine. Extreme collapse quickly supervened, with coldness and lividity of the hands and feet, and a very diffuse light cyanosis over a great part of the body. Tenderness was at first diffuse, but later became more marked in the upper part of the abdomen, where some diffuse swelling might occur which was soon masked by general distension. In a large majority of the cases it was not possible to make a diagnosis, but a history of previous alcoholism in a middle-aged man with such symptoms might be suggestive. It required early and prompt operation for its treatment, since it was a very fatal malady, the patient dying collapsed at the end of two or three days. In the second group, the subacute or suppurative type of case, the onset was less acute and fulminant in character; the pain was less severe, there were fever, chill, and leucocytosis, and the gradual development of a tumour mass in the upper part of the abdomen. The examination of the fæces and the urine might help in the diagnosis; in the former there might be fragments of necrotic pancreas with a fatty character of the stools. In regard to prognosis Ebner, from a study of 96 cases, found that 90 per cent. of those not operated upon died, while 52·8 per cent. were saved by operation. The prognosis was most serious in those cases with gall-stones. The points he would suggest for discussion were the symptoms associated with acute pancreatitis, its etiology, th value of the examination of the fæces and urine, and th question of operation.

Dr. P. J. CAMMIDGE (London) had been much struck b the small proportion in which a diagnosis was made befor death or operation. On examining the records of 50 recen cases he found that 12 had been regarded as perforated gastri ulcer, 12 as intestinal obstruction, four as acute peritonitis two as appendicitis, two as cholecystitis, one as strangulate hernia, one as angina pectoris, while in 11 no diagnosi had been arrived at, and in five the diagnosis had been made and confirmed. It was therefore important to discover some aid to diagnosis. An examination of the fæces, which might be expected to afford assistance, was usually impossible owing to the constipation which was the rule; in chronic cases there was a large excess of undigested muscle fibre and of fat, especially an excess of unsaponified fat over the saponified. As far as he had been able to find out in acute cases these conditions were not present; indeed, rather the reverse might be the case. With regard to the urine he had examined it in seven cases of acute pancreatitis, in one of the subacute form of the disease, and in one case of glycosuria following upon recovery after acute pancreatitis. In four of these cases there was a considerable amount of acetone and of diacetic acid, in five a large number of calcium oxalate crystals, in four bile, and in five urobilin. He thought that the presence of urobilin was an evidence of catarrh spreading into the bile passages and pancreatic duct. Wolsey had stated that a temporary glycosuria might be seen in 10 per cent. of these cases in the first day or two. Dr. Cammidge then referred to the so-called "pancreatic reaction" described by himself in 1904 and improved in 1906. Five of his cases had been examined by the original method, in which there was a serious personal element,

APPENDIX.

The technique of the ammonio-silver method with gold-toning and cyanide decolourization.—Place thin slices of tissue in Heidenhain's sublimate solution. After from 12 to 24 hours wash the pieces shortly in water and place them in 80 per cent. alcohol (made with absolute alcohol), to which iodine dissolved in absolute alcohol has been added until the fluid has the colour of pale sherry. Renew this fluid daily until it ceases to be decolourized (generally from four to six days). Then place the tissues in 80 per cent. alcohol without iodine. After 24 hours transfer them to 5 per cent. formalin in water. In this they may remain for an indefinite period, but at least one day must elapse before the next stage is proceeded with. Place a piece of tissue in a bowl of water (which should be changed at least once) for from two to three hours. Make the ammonio-silver solution by adding 5 per cent. ammonia to 5 per cent. silver nitrate in distilled water, until the precipitate which at first forms is completely dissolved; then add more silver nitrate until a distinct cloudiness returns. Filter this solution into a bottle or specimen tube, add the piece of tissue and put the bottle, tightly corked, in the incubator at 37° C. for seven days. The silvering may thereafter be continued in the cold if it is not convenient to go on at once to the next stage. Place a piece of the impregnated tissue in a bowl of water (500 cubic centimetres) to which about two cubic centimetres of 5 per cent. ammonia have been added. Remove the surface deposit as far as possible. This is best done simply with the aid of the fingers whilst the piece of tissue is held under water. Transfer the piece to a second bowl of ammonia and water. Renew the fluid after about an hour and leave the tissue in this for three or four hours longer. Transfer to dextrine solution (dextrine five ounces or 140 grammes, water ten ounces or 280 cubic centimetres; dissolve by boiling; filter the solution through cotton-wool while still hot; after it has cooled add 1 per cent. of carbolic acid) to which ammonia has been added in the proportion of ten drops of a 5 per cent. solution to one ounce, immediately before use. Allow the tissue to remain in this for from 12 to 24 hours. Cut thin sections on the freezing microtome. Transfer them from the knife to a bowl of water to which about ten drops of 5 per cent. ammonia have been added. After about five minutes transfer the sections to another bowl of ammonia and water, and after a similar period give them a third wash. Transfer the sections to a bowl of water to which there have been added from five to ten drops of a saturated solution of citric acid in water, and allow them to remain in this for four or five minutes. Place the sections in a bowl of tap water and after a few minutes transfer them to a second bowl of water. They are now ready for toning.

The reagents required for the toning and decolourization processes are 1 per cent. solution of gold chloride in distilled water, 1 per cent. solution of pure sodium tungstate in distilled water (it is necessary to effect the solution of the salt by boiling), and 1 per cent. potassium cyanide in distilled water. Using only a clean glass rod or platinum needle, place from six to 12 sections in a watch-glass containing a mixture (carefully filtered) of the sodium tungstate and gold chloride solutions in equal portions. Allow the sections to tone for about half an hour, or until they assume a distinct red tint, and then transfer them to a bowl of water in which they should be allowed to wash for some minutes. Next place the sections one at a time in a watch-glass containing a little of the cyanide solution. When the section has lost its deep red colour and assumed a light pink tint, transfer it to a bowl of water and allow it to wash for from ten to 15 minutes, giving at least one change of water. Next stain the section for from five to ten seconds in Löffler's or Neisser's methylene blue, wash it well in water, dehydrate with absolute alcohol, clear in equal parts of turpentine and benzol, and mount in benzol-balsam.

Edinburgh.

AT a special court of the governors of the North-West London Hospital held at the institution on July 31st, Lord Rathmore being in the chair, it was unanimously resolved to act on the recommendation of King Edward's Hospital Fund to amalgamate the hospital with the Hampstead General Hospital. The present building in the Kentish Town-road will be reserved, we understand, as an out-patient department.

A STUDY OF THE CONDITIONS PRODUCING THE ANOMALOUS REACTION NOT INFREQUENTLY MET WITH ON TESTING URINE FOR SUGAR WITH FEHLING'S SOLUTION.

By F. W. PAVY, M.D. LOND., LL.D., F.R.S.,

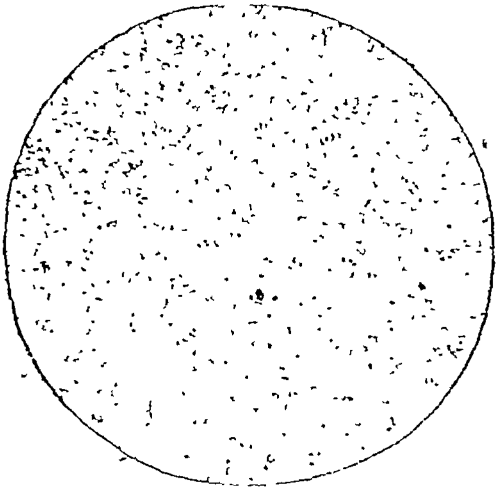
CONSULTING PHYSICIAN TO GUY'S HOSPITAL; HONORARY PHYSICIAN TO KING EDWARD VII. HOSPITAL.

(Concluded from p. 293.)

STUDY APPLIED TO THE URINE.

THE details that have been entered into may be regarded as constituting a foundation for the study of what must be spoken of as the complicated conditions existing in connexion with the urine. It has been shown that when dextrose is dealt with in a pure state the suboxide of copper produced becomes deposited in a more or less crystalline form. There being nothing to interfere with the normal procedure of coalescence, the particles of the newly formed suboxide cohere in a definite manner and lead to the production, when not too hurriedly thrown out, of bodies seen by the microscope to possess a quadrilateral shape. A widely different result is observed when dextrose is present in urine. The associated constituents, by their influence upon the coalescing process, physically alter the character of the precipitate both as regards colour and form. Instead of the vermilion-coloured deposit of the form above described it is noticeable, as regards form, that no matter what the amount of sugar present the precipitate thrown down is of an infinitely finer nature, and, as regards colour, that this varies with the amount of sugar present, beginning with yellow and passing to orange yellow, orange red, brick red, and where much surplus sugar exists to be caramelised by the alkali of the test to brown and brownish black. Throughout in these instances nothing at all resembling the normal type of precipitate is discernible on microscopic examination. Fig. 6 displays a representation of the microscopic appearance of the suboxide precipitate obtained from urine containing 50 per 1000 of sugar.

FIG. 6.



It is thus seen that the effect of the urinary constituents is in all cases, whether the amount of sugar is large or small, to produce a marked alteration from the normal type of suboxide precipitate, and that the alteration is heightened in proportion as the amount of sugar is lessened. In this way the deviation from the normal type gradually becomes more and more pronounced until the anomalous reaction is reached. Furthermore, when this is arrived at the progression of deviation is still carried on upon the same lines as before. As the amount of sugar present is smaller, so there is a more altered kind of reaction produced. For instance, after more or less delay of precipitation, a point to which I will refer later, the contents of the test-tube may i.e., inflammatory conditions of the gums and mouth due to the *streptococcus* and *staphylococcus*—in increasing the severity of the primary and secondary angina of scarlet fever. He recommended extreme and rigid antiseptic treatment of the mouth when oral sepsis was found to be present in cases of scarlet fever.

Dr. TYSON read a paper entitled

Some Remarks on the Prevention of Appendicitis.

He gave statistics showing that of recent years appendicitis had increased in frequency both absolutely and relatively and that it tended to be more severe in type. He referred to the difficulty in persuading people to adopt preventive treatment in the form of proper regulation of diet and exercise. Appendicitis was a disease of civilised life, being rarely met with in the coloured races in America and Africa. He attributed the increase of the disease to the following conditions: oral sepsis, excessive eating, and the eating of unsuitable foods, such as too soft foods and frozen articles of diet, alcoholism, and the faulty position adopted in the act of defæcation. He suggested appropriate means regarding all these conditions in order to endeavour to lessen the frequency of the incidence of the disease.

SURGERY.

WEDNESDAY, JULY 31ST.

Mr. GEORGE A. WRIGHT (Manchester), the President of the section, opened the meeting with a short speech in which he expressed his thanks for the honour which had been done him in appointing him to the post.

A discussion on

The Relative Value of Inhalation and Injection Methods of Inducing Anæsthesia

was to have been opened by Mr. H. P. DEAN (London), but in his absence his paper was read by Mr. W. SAMPSON HANDLEY (London), one of the secretaries of the section. Mr. Dean mentioned that he presumed he had been chosen to open the discussion in consequence of his having written a paper on the Value of Lumbar Injection in Acute Abdominal Diseases and therefore he had considered it advisable to limit himself to spinal analgesia. The point which had struck him the most in operations under spinal anæsthesia had been the great mitigation of surgical shock; it might almost be said that shock had been practically abolished. The operations which were most frequently followed by shock were those connected with the abdominal cavity, though it was necessary to include a few others, such as those on the thigh, the hip, and the knee, but most of these operations were much less frequent than they were 40 years ago. Trans-sacral excision of the rectum must also be included. When ether and chloroform were first introduced it was soon noticed that although the pain of the operation was not felt the amount of shock was almost as great as in the pre-anæsthetic days. It must also be remembered that both ether and chloroform were liable to give rise to troublesome after-effects as in the bronchial mucous membrane and these were especially troublesome in cases where an abdominal operation had been performed. Chloroform and ether affected primarily the higher nerve centres, especially those connected with consciousness; then the basal ganglia were affected; later the sensory and motor tracts; and, lastly, if the anæsthetic had been pushed too far, the centres necessary for maintaining life, those connected with the heart and lungs, were involved. In the choice of an anæsthetic they should look for one which would not irritate the respiratory mucous membrane, and also they should choose one which would paralyse completely all the afferent nerves coming from the area to be operated on. If the peripheral nerves of the affected part were completely thrown out of action no amount of damage could cause stimuli to pass to the central nervous system; at the same time consciousness and the integrity of the vital centres would be maintained. Within the last few years several drugs had been discovered possessing the power of paralysing the peripheral nerves without affecting the central nervous system. Cocaine was the first, but it was very poisonous and uncertain, and it was unsuitable. Beta eucaine was not much better. With[illegible] two years a more suitable drug had been [illegible] was [illegible] and a similar substance [illegible] novocaine. Stovaine [illegible] rather than a depressing effect on the heart. The formula that Mr. Dean preferred was stovaine 0·1 gramme, sodium chloride 0·1 gramme, and distilled water 1 gramme. It was unnecessary to discuss whether spinal anæsthesia should replace general anæsthesia in the ordinary operations of surgery. It was largely a question of sentiment; there certainly were patients who did not like having their "senses taken away," and for these spinal anæsthesia might be used. When, however, they were dealing with acute abdominal diseases, such as acute general peritonitis, the matter was different. They did not get the harmful irritation of the respiratory mucous membrane, nor the severe secondary effects of the anæsthetic, and, most important of all, the thorough paralysis of the peripheral nerves protected the patient from nearly all of the surgical shock. In this country spinal anæsthesia had made very little headway, and this was strange when they considered how extensively it was employed abroad. Mr. Dean's paper then considered the chief points in connexion with spinal anæsthesia. The injection was best made between the third and fourth lumbar vertebræ; if it was done higher there was some risk of injuring the cord; if it was given very low there was a possibility of the anæsthesia being unilateral. The exploring needle, which was better than a trocar, might puncture a vein, for there was an extensive venous plexus in that neighbourhood and the bleeding might be troublesome. It was often advised that a little fluid should be allowed to escape first, and it was a fact that the headache which not rarely followed spinal anæsthesia was caused by increase of cerebro-spinal pressure. Mr. Dean had three exploring needles of different lengths so as to suit different cases. It was important to screen the operation from the sight of the patient, and for this purpose a small cardboard screen was sufficient; it was well also for a nurse to sit beside the patient and engage his attention, so as to prevent him listening to what was said. The opinions of some patients who had had spinal anæsthesia for acute general peritonitis and other conditions were read, and they all agreed in saying that though they felt the prick of the needle they felt nothing else; they preferred spinal analgesia to a general anæsthetic. The least dose which appeared to be of any practical value was 0·05 gramme. The following method was convenient in, say, acute general peritonitis: begin with 0·6 cubic centimetre of the solution; if in seven minutes anæsthesia was not present give 0·3 cubic centimetre more; if seven minutes later the anæsthesia was still incomplete give 0·3 cubic centimetre more. If even then there was not sufficient anæsthesia the drug must be at fault or there was some other disturbing cause. For instance, it had been found that if the exploring needle had been boiled in a solution of sodium carbonate the stovaine loses all its power. The needle might be left in during the operation and additional doses might be given if necessary. Though he had never found it necessary it might sometimes be advisable to give a dose after the completion of the operation if there were a recurrence of the pain. The surgeon could fully rely on the anæsthesia produced by lumbar injection for any operation not higher than the umbilicus. One of the most important points in connexion with spinal anæsthesia was the absence of shock.

Dr. J. WARD COUSINS (Portsmouth) agreed that it was very remarkable that on the Continent of Europe spinal anæsthesia was very widely used but very little in this country. It is certain that the dangers from general anæsthesia were grave but spinal anæsthesia was not safe either and the decision as to which should be employed must depend in great part on the relative mortality. He had seen a statement that in 2000 cases treated recently by spinal anæsthesia there had been six deaths. Shock certainly seemed to be reduced in spinal anæsthesia but he was inclined to think that the possession of consciousness might cause a good deal of shock in highly nervous patients. It was very probable that mere manipulation of the abdominal organs might cause distress in patients under spinal analgesia, especially if the operation was prolonged. Probably if the decision were left to the patients most wo[illegible] prefer the general anæsthetics.

Mr. ALEXANDER WILSON (Manchester) thought that patients under a general anæsthetic suffer much from shock, and if spinal anæsthesia did prevent shock it must be preferable on that point at least. He, however, pointed out that when all things were taken into consideration general anæsthetics were really very safe. He felt sure that, as a rule, too deep a degree of anæsthesia was maintained. He [illegible]

From all sides it is seen that evidence stands forth pointing to ammonia constituting a factor concerned in the production of the modified reaction being referred to. As a natural consequence it follows that in the presence of ammonia precipitation is inhibited as long as sufficient is present for the purpose. When this ceases, through dissipation by boiling, to be the case the copper suboxide comes into view.

To epitomise, we have clearly two events to deal with in connexion with the modified reaction under consideration, one being the inhibition of precipitation and the other the production of an altered form of precipitate. How far these two events are primarily connected constitutes a problem that may be regarded as open for solution. Doubtless creatinine is the prime agent at the foundation of the production of the modified form of precipitate. As I have shown, it possesses great power as an inhibitor of suboxide coalescence. Now, with regard to the inhibition of coalescence, it is easy to comprehend the *rationale* of the phenomenon as long as visible matter has to be dealt with. It is demonstrable by the aid of the microscope that the degree of fineness of the product stands in proportion to the extent to which coalescence has been interfered with. I have previously discussed this question and have suggested that by an extension of the process of interference we become carried to the state existing in the case of a solution. Have we not here particles of a substance, so minute as to be invisible, held apart by the attraction influence of the elementary material of the solvent, which must of necessity be greater than the attraction power that leads to self coalescence? It is conceivable that creatinine as an inhibitor of coalescence may carry on the inhibition to an extent to affect the elements of the body concerned before coalescence has sufficiently advanced to give a visual something to be dealt with. In such circumstances we are supplied with a representation of the physical condition of solution, and possibly in the presence of a large quantity of creatinine on the one hand, or of a minute quantity of suboxide on the other, by the mechanism in question, newly-formed suboxide might be concealed from view. The amount of creatinine, however, existing in urine I consider may be taken to be inadequate for the production of such a result.

It is known that by altering the relative amounts of Fehling's solution and urine different results are obtainable when only small quantities of sugar are present. The difference may be such that by one mode of testing the urine may appear to be free from sugar whilst by another a pronounced reaction may speedily show itself. The experienced clinician can excite surprise by modifying at will the character of the result produced. Dr. Kellas and Dr. Wethered dilate upon the point mentioned and give[3] a number of experimental representations of the result obtained with the employment of altered relative quantities of urine and test solution. The effect of the urine being in undue quantity in relation to the test solution is to promote the occurrence of a reaction when none might be visible if the test solution stood in larger relative amount to the urine. I agree with Dr. Kellas and Dr. Wethered in considering that the best standard procedure is to employ equal quantities of urine and test. I am also of opinion that they stand upon right ground in suggesting that high specific gravity urines create a demand for an increased proportionate quantity of the test solution to bring them into a parallel position with equal quantities for average specific gravity urine.

What, it may be asked, is the explanation of the varying results to which I have just been alluding? I think the explanation can be given and I propose to pass to its consideration. The actual circumstances before us are that a show of reaction is restrained in one case in a manner that does not occur in the other. In both cases the sugar is present; in the one case it is revealed, in the other it is not. All urine contains sugar, but we are accustomed to speak of it as free from sugar because it does not give a reaction under the ordinary mode of testing employed. It may be said to be fortunate that things stand as they do, for otherwise diagnostic uncertainties might present themselves where none now exist.

Why is it that the sugar known to be present is not revealed by the Fehling's test? This is the problem before us. It is not in reality on account of the want of delicacy of the test reagent, for this, as we know, is delicate enough to reveal an infinitely smaller quantity of sugar than that present in the urine when existing in a state of pure solution. The test solution contains a fixed alkali, and the urine contains nitrogenous matter from which ammonia is liberated during the process of boiling that is carrried out in the application of the test. We have here something to exert a restraining influence on the precipitation of the suboxide, and often it may be seen in testing urine that there is more or less fading of the blue colour of the test, which means that reduction without precipitation has occurred. By long enough boiling precipitation is found to take place. It follows that the larger the amount of test solution present the greater the restraining power in operation on precipitation. Thus no precipitation may occur with the employment of the larger apportionment of the test solution, whilst with the smaller, which entails the presence of a less amount of alkali, precipitation may be observed to take place.

It is the alkali in the test solution that is productive of the effect described, and instead of employing the extra amount of Fehling's solution the result may be brought about by the addition of a few drops of a strong solution of potash. To a specimen of urine giving a somewhat delayed precipitation, if, say, two drops of a 40 per cent. potash solution be added, precipitation is found to be further delayed. The potash restrains precipitation, deductively through leading to the development of ammonia, and if too much potash be used the production of the proper reaction belonging to the test is profoundly interfered with. To promote escape from the reaction producible by the sugar normally present in the urine it is desirable that precipitation should not with too great facility occur, and upon this ground I consider that more alkali should be present than that which is contained in the Fehling's solution in ordinary use. In the liquid that I have from a very early period been in the habit of myself employing the amount of alkali is such, reckoning it to consist of potash, as to stand in the proportion of 170 to the 100 representative of the amount in the ordinary Fehling's solution. I consider it supplies a more dependable and thereby a better liquid. The composition of my solution is as follows:—

Pavy-Fehling's Solution.

Copper sulphate (crystallised)	34·65	grammes.
Potassium sodium tartrate (Rochelle salt) ...	170·00	„
Caustic potash	170·00	„

Distilled water to 1 litre.

I suggest that the question of the amount of alkali in Fehling's solution to which I have been referring is one that is deserving of consideration by others and am decidedly of opinion that the larger amount spoken of leads to the production of a more trustworthy test liquid for urinary application. It must be borne in mind in connexion with this matter that we are confronted with a pitfall on either side. With too little alkali the indication of normal sugar is favoured and with too much alkali sugar present to an abnormal extent may fail to be indicated on account of the restraining effect exerted on the reaction. It behoves us, therefore, in avoiding Scylla to escape from falling into Charybdis.

There is another point to mention touching the respective merits of the two liquids. It is often noticeable on adding Allen's Fehling solution to specimens of urine in equal quantities that a more or less considerable amount of a flocculent precipitate is produced, which becomes rather increased on heating. The deposition is prevented by a little extra alkali and does not ordinarily occur with my own liquid.

THE BEARINGS OF THE SUGAR NORMALLY PRESENT IN THE URINE.

The presence of sugar as a constituent of normal urine is no longer open to controversy. With the advance of knowledge, the means that have been placed at our disposal for the recognition of sugar are now such as to establish incontrovertibly the point and dispense with the necessity of adverting to the discussion that in former days took place. We stand upon new ground in connexion with the matter but at the same time it is noticeable that a disposition exists to minimise the accepted condition to an unjust extent. For instance, I notice that Dr. Kellas and Dr. Wethered in their communication to THE LANCET already alluded to only grudgingly, as it were, assent to sugar being regarded as a constituent of normal urine. At page 1058 they say: "As a result of a careful review of the whole field of argument we have been led to the conclusion that a small gangrenous, and when further bowel was drawn down it was found that there were more than nine feet of gangrenous bowel extending to within two inches of the ileo-cæcal valve. This was removed and the ends were closed and a lateral anastomosis of the small intestine into the large was made. The patient recovered, and though she lost weight for a time she had now ceased to get thinner. There was a great tendency to diarrhœa which was checked with morphine. Mr. Childe attributed the gangrene to an embolus of the superior mesenteric, and he considered its association with the hernia to be accidental.

---

STATE MEDICINE.

THURSDAY, AUGUST 1ST.

A paper was read by Professor H. R. KENWOOD (London) on

The Reduction of Infant Mortality by the Better Management and Control of the Milk supply.

Professor Kenwood commenced by pointing out that cows' milk in its untreated state was not a suitable food for infants and was fraught with great dangers. It must not, however, be assumed that the mortality among hand-fed as compared with breast-fed infants was mainly due to this cause, as the factors of infantile mortality were many and complex. The community had, however, a right to require that the milch cows should be healthy, their surroundings sanitary, and their milk fairly clean, coupled with an absence of chemical preservatives. So far the milk trade had not been fully alive to the demand made upon them or to the exceptional position which they held as the vendors of a unique commodity. It was undoubtedly a very difficult trade to conduct, but the public had a right to demand some effort to conduct it properly, and it should cease to be regarded as a danger to infant life and health. The danger began at the source and there was no doubt of the appalling ignorance which prevailed on dairy farms. To those who were acquainted with the methods pursued in Denmark the conditions prevailing in England were absurd and horrible, and the milk reached the distributor in a state of absolute dirt, which was very bad indeed. Milk could not be kept wholly free from micro-organisms, but the present proportion was capable of material reduction and their further multiplication during distribution and transit could be materially checked, even if a standard of perfection could not be attained. In the absence of proper inspection and supervision by rural sanitary authorities it might be possible for the milk trade themselves to influence the farmer or in some measure to educate him. This had already been done by many of the large milk dealers and with excellent result. But it was unfair that this burden should be laid upon any trade and as it was to the interest of the community to protect the purity of milk it was the duty of the State to insure it and not to relegate its duties to private individuals. At the present time 20 per cent. of the authorities concerned had not even adopted the regulations of 1885. It was thus evident that some compelling statute was required and that proper Government supervision was quite as necessary as it was in the case of adulteration of food and drugs. Milkshops should be licensed, not as at present simply registered, and the licence must be subject to annual renewal; it would then be possible to require an initial standard of cleanliness and to see that it was maintained. The systematic inspection of milch cows should be made at intervals of not less than three months by a veterinary inspector under the Board of Agriculture, and tuberculous animals should be segregated and slaughtered; a reasonable scale of compensation might be granted. Professor Kenwood then discussed the pasteurisation of milk and the compulsory sale of milk in bottles, by which means much contamination in the home might be prevented, while the bottle was a guarantee of full measure and watering was rendered less easy. The dangers arising from feeding infants on sterilised milk had probably been exaggerated, for the evidence was very small of the actual existence of any real danger. He was not enthusiastic in favour of milk depôts and considered that the infants' "consultations" and similar measures recently adopted in St. Pancras were much to be preferred. He finally alluded to the promise made by Mr. Burns to introduce legislation next year and trusted that such legislation would be stringent and far-reaching and would, above all, embrace proper inspection of dairy farms and milch cows.

Dr. E. W. ROUTLEY (Aldershot) contributed a paper on

The Home Contamination of Milk,

which was read by Mr. J. H. GIBSON (Aldershot). He commenced by classifying the causes of infantile mortality under the following heads: wasting diseases, diarrhœa, lung disease, brain diseases, infectious diseases, tuberculosis, and other diseases, and pointing out that under these headings he proposed to deal mainly with causes producing fatal diarrhœa. Infantile diarrhœa was mainly concerned with the home conditions of the people and this was borne out by the experiences of Aldershot. Here there was a town population of 19,000 and a camp of 15,000. The town in five years showed 62 fatal cases of infantile diarrhœa against only 17 in the camp. During the same period the total deaths under one year of age were 76 and 23 respectively. The source of the milk-supply was identical in both cases and was mostly rail-carried, only about one-tenth coming from the neighbouring farms. Thus it became necessary to seek carefully for some definite cause which would account for the different rates of infantile mortality. Dr. Routley considered that this was to be found in the distinction in the methods adopted for milk storage and the standard of sanitation enforced in the camp as against the town. A careful inquiry showed that in the town no precautions were taken to keep the milk pure and clean after it had been received into the house; overcrowded rooms, tightly closed windows, free access to flies, and general uncleanliness all pointed to great home contamination. This state of things naturally produced a condition of milk admirably calculated to produce gastric and intestinal disease among children. It would therefore appear that however necessary it might be to inspect milch cows it was more important to deal with home storage.

Mr. HERBERT JONES (Hereford) felt that Dr. Routley had been fortunate in possessing so excellent an opportunity of making a comparison between two neighbouring populations but he was unable to follow him in his ultimate conclusions. Pasteurisation, as recommended by Dr. Kenwood, was excellent but they could not rely upon it because it was a remedy. What they wanted was to prevent contamination at the source. He did not think county councils were to be trusted in this matter as experience had shown by their inaction in sanitary matters. The proper controlling officer was the medical officer of health, to whom a free hand should be given without danger to his appointments. Attention should be given not only to the cows but to the water-supply and the methods employed in washing cans and travelling churns.

Lieutenant-Colonel A. M. DAVIES, R.A.M.C., spoke briefly on the necessity of careful attention to detail in the cleanliness of cowsheds; this could be done even in India and in such an impossible place as Aden. As to the dangers of sterilised milk he felt that many men had displayed a lack of proportion in studying this question.

Dr. HELEN MCMURCHY (Toronto) wished to differ so far as Canada was concerned from the views of Dr. Routley. The question of Canadian milk-supply was still in its infancy; diarrhœa in Toronto was not at all confined to poor houses. Milk in Canada was largely refrigerated and distributed in closed bottles, but even so there were occasional failures to sterilise these bottles. She had no sympathy with the cry of harassing the trade and thought that after all the remedy lay really in the hands of the community.

Mr. H. H. TIDSWELL (Torquay) related his experience of the Liverpool cowsheds which were properly paved and washed and the cows were properly groomed. He did not consider it possible to sterilise milk in all instances; he also said he had abandoned his prejudice against condensed milk, which he had found an excellent substitute for the breast.

Professor T. A. STARKEY (Montreal) desired to speak on two points: (1) the prevalence of diarrhœa in hot dry weather; and (2) the attribution of diarrhœal disease to home rather than central contamination. From practical experience in Montreal he had found that so-called summer diarrhœa was more a question of general sanitation than of temperature and that dust was perhaps the greatest causative factor. He did not boast of the milk stores in Montreal and he wished to eliminate that factor.

Dr. F. M. SANDWITH (Cairo) pointed out that mothers were becoming increasingly unable or unwilling to nurse their infants and consequently the provision of milk was more important to the community. There was milk sold in London supplied at exceptional prices which came from the very worst dairies. In America much had been done to protect the milk-supply of great cities; the lead had there been that reactions may be obtained, giving rise to suspicion that an abnormal glycosuric state exists. In an extreme case of low specific gravity urine—viz., one in which it stood at 1002—the sugar indication stood at 0·34 per 1000.

I have stated that in the case of normal urine the cupric-oxide reducing power shown to exist before and after hydrolysis stands ordinarily in the relation of about 60 to 100. The symbol K is used to represent this relation, a body with a cupric-oxide reducing power of, say, 60 before hydrolysis which becomes raised to 100 by conversion into glucose, being spoken of as possessing a K value of 60. In the fasting animal it is noticeable that K stands at a lower point than in the fed animal. In one of my observations upon the rabbit, the one that has been referred to above as giving the lowest cupric-oxide reducing figures, it was noticed that K stood as low as 38, the cupric-oxide reducing power before hydrolysis being 0·68 per 1000 and 1·80 after. In another instance it stood at 42, the figures before and after hydrolysis being respectively 3·70 and 7·90 per 1000.

In mild glycosurics where the urine may give a traceable indication of sugar with Fehling's solution it may be mentioned as a noteworthy point that K stands higher than in the actually normal condition. The initial titration figures may not be higher than those that may possibly be met with in concentrated urine from the healthy person, but the figures after hydrolysis do not show the extent of rise that occurs in the case of normal urine. This means that there is a larger proportion of glucose in the carbohydrate that is present, and it is the elimination of carbohydrate in the glucose form that constitutes the particular feature appertaining to abnormal glycosuria.

I have given in my work, from which I have been drawing examples, a series of ten observations to illustrate the point in question. The mean of the K figures belonging to the series stands practically at 80, the lowest figure in the series being 67 and the highest 88. There are two examples with a K of 88. Taking one of these two, the figures before hydrolysis were 7·69 and after 8·72. I refer to this example to show the contrast with the condition in the normal rabbit's urine referred to above, where the figures before hydrolysis were 8·80 and after 16·54, giving a K of 53. As the abnormal variety of glycosuria attains greater intensity K becomes higher and higher until the glucose so overpowers everything else as to lead to the same figures being obtained before and after hydrolysis, as is found to be the case in pronounced diabetes.

Dr. Kellas and Dr. Wethered[3] extol the safranin test and think that it "deserves to come into more general use." Being unaffected by creatinine and uric acid, they speak of it as a more scientific test than Fehling's solution. This is so far true, but it happens to be of sufficient delicacy to give, as stated by them, more or less reaction with ordinary urine. It is just this character which, in my opinion, renders it unsuited for clinical use and I feel that much danger of frequent error would be incurred if its employment in a general way were adopted. The great value, I consider, of Fehling's solution is that the sugar normally present in urine escapes being revealed except under the existence of special circumstances. In these circumstances, mainly consisting of undue concentration of the urine, whilst only a slight reaction may be given by Fehling's solution, a full reaction would be given by the safranin test with exclusion of the opportunity of seeing any gradational indication.

Assuming that a slight reaction is given by Fehling's solution the question naturally presents itself, does it constitute an exaggerated normal reaction or is it the result of an abnormal condition? To give full opportunity for a trace of reaction to show itself the contents of the test-tube should be briskly boiled for a short time and the tube looked at after being allowed to stand aside for a few minutes. Over and over again it is found, on adopting this procedure, that at the end of boiling there may be no sign of precipitate to be seen, whilst on standing a precipitate comes into view. The scientific way of ascertaining the true significance of a doubtful reaction is through the medium of a test-meal. If two or three hours after a plentiful allowance of starchy matter and sugar has been taken, there is no effect produced upon the urine, it may be concluded that nothing abnormal exists.

A METHOD OF AMPUTATION AT THE ANKLE-JOINT WHICH LEAVES THE HEEL INTACT.

WITH A REPORT OF TWO CASES OPERATED UPON AND SHOWN AT THE CLINICAL SOCIETY OF LONDON ON APRIL 24TH, 1907.

BY C. GORDON WATSON, F.R.C.S. ENG.,
SURGEON TO THE METROPOLITAN HOSPITAL AND SURGICAL REGISTRAR AT ST. BARTHOLOMEW'S HOSPITAL.

THE method here given was made use of in the two cases described below for long-standing talipes equino-varus, with equinus predominating. In both cases the deformity had been untreated in the past and owing to the stretched and enfeebled condition of the extensors and the shortened and contracted condition of the flexors offered little chance of improvement without relapse, so long as an ankle-joint remained, which would allow the flexors again to overpower the extensors. The operation resembles in many respects le Fort's modification of Pirogoff's operation and may be termed "trans-calcaneal amputation of the foot."

Details of the operation.—For the anterior flap three points are taken as follows: half an inch below and half an inch behind the tip of the internal malleolus, a quarter of an inch below the tip of the external malleolus, and one and a half inches below the mid-point of a line joining the tips of the two malleoli across the dorsum. A semilunar flap is then cut joining these three points. The plantar flap is then cut by an incision dividing skin only, which extends from the inner extremity of the anterior flap downwards and forwards to half an inch in front of the prominence of the tubercle of the scaphoid, then transversely across the sole to half an inch in front of the prominence of the base of the fifth metatarsal, and then straight back to the outer extremity of the anterior flap. The anterior flap is then dissected up, the extensor tendons are divided, the anterior tibial and musculo-cutaneous nerves are cut short, and the dorsalis pedis artery is ligatured. The ankle-joint is then opened from the front and the foot is forcibly depressed (the equinus position greatly facilitates this stage of the operation), the internal lateral ligament is severed from its attachments to the astragalus, with the edge of the knife held close to the bone, and the anterior and middle fasciculi of the external lateral are similarly dealt with; then with the foot inverted the knife is passed from without between the os calcis and astragalus and the interosseous ligament is divided. The astragalo-scaphoid joint is now opened and the head of the astragalus is freed from the scaphoid. The body of the astragalus is next seized with lion forceps and twisted round so as to detach it from the posterior fasciculus of the external lateral ligament and the posterior ligament and so removed.

The next step is tenotomy of the tendo Achillis and all contracted fibrous tissue around it, taking great care to avoid the posterior tibial vessels and nerve. It will then be seen that the os calcis can be brought up to the lower surface of the tibia, except for the projection of the sustentaculum tali which comes into contact with the internal malleolus. With a broad gouge the cartilage is then removed from the lower surface of the tibia, working from within outwards so that the gouge is checked against the internal surface of the external malleolus, and then the malleoli are cleared of cartilage and the posterior inferior tibio-fibular ligament is removed. Next, with the foot well depressed and pulled forwards, the upper articular surface of the os calcis is cleared of cartilage either by sawing off a thin slice with a fine saw or with a gouge. Owing to the slope of this surface it is necessary to take a little bone as well from the posterior part of this surface. The sinus pedis is then cleared of all fibres of the interosseous ligament and extensor brevis digitorum. Then so much of the sustentaculum tali is cut obliquely as will allow the os calcis to fit into the hollow between the malleoli.

Up to this point the front of the foot has been left articulated to the os calcis for purposes of manipulation. The os calcis is now disarticulated from the cuboid and the separation of the foot is completed by cutting obliquely through the soft tissues of the sole to the margin of the skin flap already marked out. Before fixing the os calcis to the tibia the plantar vessels are tied, the plantar nerves are cut short, the tourniquet is removed, and all bleeding points are to this operation in cases of placenta prævia he was of opinion that, like ordinary Cæsarean section, it was quite uncalled for, as better results could be obtained by other methods.

Professor PAUL STRASSMANN (Berlin) stated that the opinion held in Germany at the present time coincided in the main with what Dr. Jardine had said. He thought that Champetier de Ribes's bag was the best instrument for general practitioners to use. He was not at all in favour of Bozzi's dilator, having known of several most serious accidents due to its use. A celebrated pathologist had told him of a case where the body of the uterus had been ruptured by this instrument for five inches. A friend of his had asked one of the chief instrument makers in Germany who it was that bought Bozzi's dilator and had received the answer that certainly not those who had the best practices. Professor Strassmann had been present at a clinical demonstration held to show students the use of Bozzi's dilator and had seen the uterus ruptured during the dilatation. When the cervical canal was very narrow he thought one of the best methods was to dilate the cervix first with a metal dilator for four numbers and then plug the cervix and vagina with iodoform gauze. In cases where it was necessary to deliver as quickly as possible, such as in some cases of eclampsia, then he thought that cervical incisions were the best, but he wished to point out whilst incisions might do for home treatment vaginal Cæsarean section could only be safely performed in hospitals with properly trained assistants. He did not use Bozzi's dilator because of the bad results which followed its use.

Dr. A. L. GALABIN (London) thought that the original method of dilatation of the cervix, manual dilatation, was the best in most cases where this operation was needed, such as rigid cervix, inertia of the uterus, and early rupture of the membranes. Dr. Galabin mentioned the case of a patient who had been in labour for a week, and although vigorous pains had been present the os was so small that it would only just admit a sound. In this case he dilated with the sound and fingers and the child was born in 12 hours. Another good plan, easily combined with manual dilatation, was during the first stage to separate the membranes over the last two inches of the lower uterine segment. There was no danger in doing this, and he thought it a very good plan to adopt when the patient had gone over term and the child was large. The advantage of Bozzi's dilator was that it did its work well in the early stages of dilatation, whereas the mechanical effect of hydrostatic dilators, being proportional to the diameter of the canal, was very small or absent when the os was not dilated. On the other hand, in the later stages Bozzi's dilator was more dangerous, the cervix being much thinner, whereas the hydrostatic bags were much more efficacious. It was, therefore, good treatment to commence dilating with a Bozzi's dilator and after a while to use a bag. Vaginal Cæsarean section should be limited to hospital practice and skilled operators.

Dr. J. M. MUNRO KERR (Glasgow) thought that the advantage of discussing such a subject as this at so late a period, other countries having done so years ago, was that it could be examined more quietly and a better opinion could be formed. In the question of this kind two lives had to be considered, that of the mother and the child. The indications for rapid dilatation in the interests of the child were certain cases where its life was threatening, such as rigid cervix, placenta prævia, and some cases of eclampsia, when the most rapid means must be applied. On the other hand, in the interest of the mother it was always best to adopt the slowest methods. Dr. Kerr considered vaginal Cæsarean section to be the most dangerous of all the methods mentioned. It was in certain cases a most valuable operation but should only be performed in hospitals. Its difficulties varied with the period of pregnancy. It was very simple up to the sixth month, taking 15 minutes or so. Later than this the difficulties appeared, especially in bringing down the uterus, and at term it was very dangerous, there being great danger of injuring the bladder unless the vagina was enlarged by deep incisions. His experience of Bozzi's dilator was that, no matter how slow the instrument was used, lacerations were certain to take place. The only safe cases for its use were when the os had commenced to dilate. Another drawback was that the canal was never so dilated as appeared from the use of the instrument. In the later months of pregnancy Dr. Kerr preferred abdominal Cæsarean section.

Dr. F. EDGE (Birmingham) said that except in cases of great urgency he would not use Bozzi's dilator. He narrated a case in which after its use the bleeding was severe and the uterus was plugged. Ten minutes later the hæmorrhage returned but on taking the plugs out and pulling down the uterus with volsellæ the bleeding stopped. He then replugged the uterus and the same thing happened. It was then discovered that the bleeding was due to a lacerated uterine artery and that the traction on the cervix with the volsella kinked the vessel and so stopped the bleeding *pro tem.* He thought that just as safety bicycles were a great improvement on bone-shakers, so Bozzi's later instruments were a great improvement on the first, and perhaps the bad results obtained by some operators were due to a bad instrument having been employed. In hospital he thought that any method most suitable to the case should be employed. In private practice the best method was to dilate manually, wearing a well-greased indiarubber glove. Dr. Edge showed a small rubber bag which could be passed into any cervical canal fixed to the end of a stylet.

Dr. J. INGLIS PARSONS (London) thought that at full term there was not the slightest doubt abdominal Cæsarean section was better than vaginal Cæsarean section.

Dr. R. J. JOHNSTONE (Belfast) did not find Bozzi's instrument so dreadful. It owed its bad repute to its being used when not necessary. He did not regard lacerations of much import if asepsis was perfect.

Professor J. A. TEMPLE (Toronto) said that the Canadian practice with respect to the subject under discussion was of a conservative character, and they had been slow to adopt cervical incision and vaginal Cæsarean section. His experience was that in most cases a little patience and time were often all that was necessary. Professor Temple thought that a large number of cases of slow dilatation were due to the membranes being adherent to the lower uterine segment. With regard to Cæsarean section he would perform abdominal section every time in preference to vaginal.

Dr. T. WILSON (Birmingham) thought that a laminaria tent was one of the best things to commence dilatation with. He had performed vaginal Cæsarean section five times, twice in the later months of pregnancy. The first case was nine years ago, before vaginal Cæsarean section, as it was now termed, had been thought of. He was called to a case where a medical man had been dilating the cervix with Hegar's dilators at term, but instead of fixing the uterus with a volsellum he had done so with his hand, with the result that the uterus was torn away partly from the vagina. In the later months he did not find vaginal Cæsarean section more difficult than abdominal.

Dr. S. J. CAMERON (Glasgow) said that he was of opinion that the degree of damage done by Bozzi's dilator varied in different cases. Thus in an eclamptic case in which 55 minutes were devoted to cervical dilatation deep laceration was found to have occurred, whereas in another instance, when complete dilatation was gained in 20 minutes, the cervix was found to be unharmed. The amount of injury occurring seemed to depend on the consistency and rigidity of the cervix. His experience was that Bozzi's dilator was not indicated in cases of accidental hæmorrhage. He could not agree that lateral cervical incisions were always attended by risk from hæmorrhage as the uterine artery branched dichotomously, and clinically lateral cervical tears were seldom attended by severe bleeding.

Professor W. C. SWAYNE (Bristol) had used Bozzi's dilator many times in his own practice, with results pleasant and the reverse. The bad results were due to using it for full dilatation; it was much safer to commence with this instrument and finish with the hands.

Professor W. E. DIXON (Cambridge) was not an obstetrician, neither had he ever dilated a cervix, but lately he had been working on alcoholic placental extracts with Dr. T. Taylor and they had obtained one which caused marked contraction of the uterus and relaxation of the cervix. He thought that this drug might be of some value to obstetricians and might perhaps take the place of instrumental dilatation in some cases. The substance he had extracted seemed to have some relation to adrenalin which also produced similar effects. In pregnancy the cortex of the suprarenal glands was much hypertrophied.

The PRESIDENT of the section said that, although the discussion had brought out the fact that dilatation of the cervix at full term was occasionally called for, yet when specific causes came to be named there appeared to be no agreement. He did not think that rigidity of the cervix was ever an indication for adopting the drastic methods recommended.

the centre and not free as in the first case. The patient commenced to walk on a peg leg five weeks after the operation, when bony union was firm and the wound was soundly healed. He began to walk on an artificial foot seven months after the operation.

Remarks.—1. It will be found that with the incision given the margin of the plantar incision will be about from one to two inches longer than the margin of the dorsal, so that in suturing slight puckering of the plantar flap will be necessary. Any attempt at lengthening the anterior flap at the expense of the plantar offers two disadvantages—danger of sloughing in the dorsal flap, which consists only of skin and is not too well supplied with blood, especially in paralytic limbs, and also a risk of getting the ultimate scar too near the sole. 2. At the completion of the operation the plane of the sole remaining will not be horizontal but tilted forwards and upwards at an angle which corresponds to the position of the os calcis and sole in the normal foot. 3. The tendo Achillis having been divided there is no likelihood of the os calcis becoming displaced backward and lateral displacement is prevented by retaining the malleoli. It is important to remove all cartilage and to get accurate adaptation of the bony surfaces before fixing. 4. The results of the two cases reported offer encouragement to repeat the operation in similar cases. The resulting stump is certainly as good as, if not better than, that produced by any other known amputation at the ankle. The operation should be applicable also to some cases of disease and injury in which it is possible to leave the os calcis. The accompanying illustrations are from Case 1.

Welbeck-street, W.

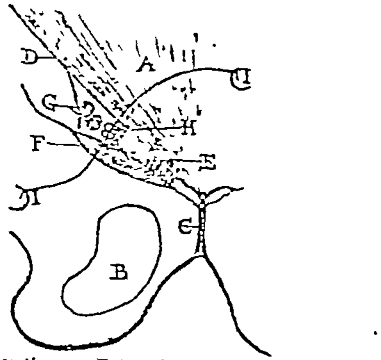
A SUGGESTION FOR THE RADICAL CURE OF FEMORAL HERNIÆ.

BY J. SIDNEY PEARSON, M.A., M.B. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,

LATE SENIOR RESIDENT MEDICAL OFFICER, ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, PLAISTOW, E.

ONE hears on all sides of the unsatisfactory nature of the usual attempts at the radical treatment of femoral herniæ so that the suggestion here made, if it does not appeal to the profession, can receive no worse fate than many others. Briefly, it consists in twisting the isolated sac, transfixing and tying it with No. 4 silk, and leaving the two ends of the silk long. Both ends are then threaded with curved needles. One end, A, is passed twice through Poupart's ligament and then out through Gimbernat's ligament, whilst the other end, B, is buried deep in the pectineus and also brought out through Gimbernat's ligament. The ends are then tightly tied and the opening is found to be securely closed. The tied sac acts as a thick plug at what appears to be the weakest point in other radical cures.

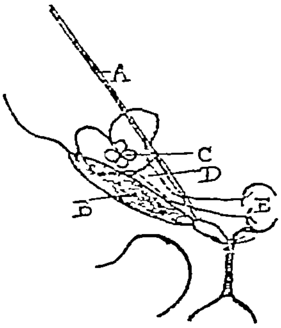
FIG. 1.



Schema of operation. A, External oblique muscle. B, Obturator foramen. C, Symphysis pubis. D, Poupart's ligament. E, Gimbernat's ligament. F, Pectineus muscle. G, Common femoral vessels. H, Sac of hernia, cut and tied. I, I, Curved needles on long suture transfixing sac.

My opportunities as resident medical officer for performing this operation have naturally been few but through the kindness of Mr. A. E. Kennedy I have operated in the above manner on two cases in females, aged 30 and 37 years, with femoral herniæ of three and five years' standing respectively. Six months in one case and four months in the other have elapsed since the operations and the wounds are quite sound with no sign of recurrence. This, of course, is no commendation for the operation. I merely wish to throw out the suggestion in case it might appeal to other surgeons of greater opportunity and experience. I may mention that this method was very easy in my own cases; I do not know how it would be in cases of strangulation or in very old people with lax tissues.

FIG. 2.



Schema of operation. A, Poupart's ligament. B, Pectineus muscle with lower suture passed. C, Stump of sac transfixed. D, Gimbernat's ligament with both sutures passed. E, Needles on ends of sutures which are ready for tying. The femoral vessels are omitted for the sake of clearness.

Sydenham, S.E.

A CASE OF STREPTOCOCCIC SEPTICÆMIA:

TREATMENT BY WRIGHT'S METHOD WITH A VACCINE MADE OF ORGANISMS OBTAINED FROM THE PATIENT'S BLOOD, THE INOCULATIONS BEING CONTROLLED BY THE OPSONIC INDEX; RECOVERY.

BY W. GREENWOOD SUTCLIFFE, F.R.C.S. ENG.,

SURGEON TO THE ROYAL SEA BATHING HOSPITAL, MARGATE;

AND

H. WANSEY BAYLY, M.R.C.S. ENG., L.R.C.P. LOND.,

DIRECTOR OF THE OPSONIC DEPARTMENT OF THE CLINICAL RESEARCH ASSOCIATION; LATE DIRECTOR OF INOCULATIONS TO THE ROYAL SEA BATHING HOSPITAL, MARGATE.

(From the Bacteriological Department, St. George's Hospital.)

THE patient, a lad, aged 14 years, was first seen by one of us on Feb. 28th, 1907, when the following history was obtained. A year previously he had been operated on for a breaking-down tuberculous gland of the neck. This wound healed and gave no trouble till December, 1906, when some discharge was noticed from the scar and some thickening detected beneath it. On examination some deeply situated tuberculous glands were found on the left side of the neck and a sinus discharging thin pus. Otherwise the boy was apparently in good health. On March 2nd the old scar with the sinus was excised and the wall of the former cavity and the deep glands were dissected out. The latter were more than usually adherent and the internal jugular was in their removal wounded and ligatured above and below the injury. On the 3rd the temperature rose to 102·6° F. The stitches were at once removed and the wound cavity was flushed out with biniodide solution. A gradual improvement took place until the 8th, when for the first time since the operation the temperature fell to normal. On the 12th the temperature rose to 103·4° and considerable discomfort was caused by a violent spasmodic cough, probably due to irritation of the vagus by the ligature. The cough persisted for several days and stopped on the silk ligature coming away. On the 16th the boy complained of pain high up in the *right* thigh, and on the following night a definite rigor took place. The rigors continued daily and on the 19th the temperature reached 105·2°. The pain in the right thigh continued but no hardness or swelling could be detected.

The question of vaccine treatment was now considered and a Wright's capsule of blood from the finger together with

Dr. INGLIS PARSONS seconded Dr. McCann's proposal, but he thought that the public also must be educated, and that it was no good educating practitioners, midwives, and so on, if the patients would not consult them.

Dr. WILSON said that he did not think that practitioners were often clever enough to diagnose early cancer even if they did examine. In his part of the country he had noticed that 50 per cent. of the cases had not been examined at all, and that of the remaining 50 per cent., 25 per cent. had not been diagnosed. He therefore thought the great thing was to instruct the practitioner. As an example of what instruction might do he might say that whereas the average number of operable cases coming under his notice up to 18 months ago had been gradually rising from 14 per cent. to 18 per cent.; during the last 18 months since he had read a paper before the local medical society on the early recognition of cancer the percentage had risen to 30. He also instructed nurses and midwives in his lectures, but did not think that leaflets should be sent out to the general public.

Dr. MUNRO KERR pointed out that the proportion of operable cases was higher when associated with pregnancy and opined that the cause of this was due to the more frequent examinations that were made in women during pregnancy, labour, and the puerperium. He thought a large number of women did not apply for advice because they were frightened of being told that they had cancer.

Dr. JOHNSTONE regarded bleeding and discharge as late signs of cancer and not early as generally given in the text-books. He did not know about the early stages here, and it should be remembered that in many cases the gynæcologist was unable to diagnose the disease before it had become inoperable. He thought that it was a good thing to alarm the medical profession, and it was not necessary that any general practitioner should be able to diagnose cancer of the uterus so much as that when any symptoms or signs arose he did not understand he should send the case for further advice.

Dr. EDGE said that if any leaflet were sent out the greatest possible care must be taken with its phraseology. Many patients did not care to be examined because they were afraid of being laughed at by the medical attendant, so that they put up with slight symptoms. The opportunity for examination should be made so easy by having female gynæcologists in different centres that women would go to them for the least trouble. Dr. Edge thought that no woman should be given the certificate of the Central Midwives Board unless it could be proved that she was able to insert a speculum into the vagina, expose the cervix, and tell whether its appearance was normal or otherwise. They might be accused that all these precautions were being advocated to benefit medical men pecuniarily, but no one made such a suggestion against dentists who advised the periodical examination of the teeth.

Dr. JOHN GILCHRIST (Glasgow) pointed out that no allusion had been made to the utility of physiological research in these cases. He thought the profession was influenced by a morphological bias. Before cancer made its appearance some physiological changes took place in the body; for instance, it had been noted in France that long before the appearance of cancer a marked inhibition in the secretion of urea took place.

Mr. CHARLES RYALL (London) said that it was known that highly satisfactory results followed radical treatment in the early stages. The anatomical position of the cervix and the free communication between its fundus and the vagina made carcinoma of this organ almost an external growth and the surgeon saw the majority of cases only when the disease was too far advanced for radical operation in spite of this fact. Of the last 100 cases of uterine cancer under his care at the Cancer Hospital, in only 24 was he able to attempt to remove the disease in spite of an extensive abdominal operation. The duration of the symptoms in the operable cases varied from hæmorrhage of one month's duration in one case to three years in two other cases. Among the 24 cases 15 had symptoms for six months or less, ten of these being for three months or under, while six had symptoms of from one to three years, all of the last class being in women who had passed the menopause. The cause of delay in seeking advice was in most cases ignorance. The public regarded cancer as an incurable disease accompanied by pain, and pain being regarded as the principal symptom the first sign, hæmorrhage, was disregarded, so that by the time pain had appeared the case was inoperable. The medical practitioner was also to blame in many cases and in several cases that had come under his observation no proper examination had been made. As a remedy he suggested (1) improvement in the teaching of the student and (2) education of the public in regard to the symptoms.

Dr. CAMERON thought that one reason why the public did not seek relief sooner was due to the fact that they considered pain to accompany disease in all cases, whereas it was a late symptom in carcinoma of the cervix. He advised (1) more thorough instruction of the students; (2) instructions to nurses and midwives in the symptoms of the disease; and (3) that central *laboratories should be* established to which practitioners could send curettings for examination by a skilled cancer pathologist. He maintained that there were two great classes of operative cases: (1) cases in which a cure might result and (2) cases in which operation was undertaken to relieve the patient of her distressing symptoms and make her closing stages more comfortable.

Dr. G. RICE (Derby) said that in his part of the country for years the cases had been sent to hospital by practitioners but since the passing of the Midwives Act a large number of people had passed out of the practitioners' hands for their confinement and had gone to midwives and that it was this class, therefore, that it was now necessary to instruct. The Central Midwives Board should be asked to see that a knowledge of the early signs of cancer was included in the schedule for examination. He also thought that midwives should be trained longer; whilst in Germany the training took three years here it took three months.

The PRESIDENT of the section was of the opinion that every nurse and midwife and most lay women knew that the early signs of cancer were bleeding and a discharge. The fault of early recognition of these cases was due to the medical attendant not being able to diagnose them. Many of them refrained from making vaginal examinations because they had no confidence that they would be able to make any diagnosis when they had. This state of affairs would never be remedied until the student was compelled to devote a larger portion of his curriculum to the study of obstetrics and gynæcology. Every medical student should attend an obstetrical and gynæcological hospital for six months and by the rules of the Irish colleges they had to, but the thing was a farce. There was no rule to make them attend so many times a week or be signed up by their teachers and a large number when they had attended 14 days and finished their cases did not go near the place again. He did not believe much in the idea of sending out pamphlets.

The PRESIDENT then put the following motion to the meeting, which had been proposed by Dr. MCCANN and seconded by Dr. INGLIS PARSONS:—

> That a committee of this section be formed to consider what steps may be taken to disseminate a knowledge of the early signs and symptoms of cancer of the uterus

An amendment to this was proposed by Dr. WILSON, seconded by Dr. SPENCER, and carried *nemine contradicente*:—

> That the Council of the British Medical Association be requested to appoint a committee to consider the best means of disseminating knowledge of the importance of the early recognition of uterine cancer.

This was then put as a substantive motion and was carried and the meeting terminated.

PSYCHOLOGICAL MEDICINE.

WEDNESDAY, JULY 31ST.

The proceedings commenced with

The Presidential Address,

delivered by Dr. T. CLAYE SHAW (London). He acknowledged the honour of being appointed president of the section and felt the responsibility of the office, which, however, he accepted with pride and gratification. The importance of these meetings must be regarded as milestones of progress and as a record of the relation of the specialty at a definite period. Their attitude of to-day was one of expectant attention, that their support and foundation was deeply fixed on the common bedrock of vital bodily processes, and that they really pulsated with *all the vibrations* of the medical system. This made them confident that, so long as they were true to their conditions in their relations with the medical and social environment they must continue to seems to confirm in every particular the conclusions arrived at by Sir James Barr, Dr. W. Blair Bell, and Captain S. R. Douglas, I.M.S., in their report in THE LANCET of Feb. 23rd last, of the first case of streptococcic septicæmia that had been successfully treated by means of a vaccine prepared and controlled by Sir A. E. Wright's method.

In conclusion, we wish to acknowledge our indebtedness to Dr. Charles Slater, bacteriologist to St. George's Hospital, for his kindness in placing the resources of his laboratory at our disposal.

Margate.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

POLYDACTYLISM.

BY WILLIAM J. MORRISH, M.D. LOND., L.R.C.P. LOND., M.R.C.S. ENG.

REFERRING to Dr. W. H. W. Attlee's case of supernumerary digits, published in THE LANCET of July 20th, p. 163, I may perhaps record the following.

On Nov. 29th, 1906, I attended a woman in her seventh confinement, the child proving to be a girl. She had previously had two boys and four girls. Both boys were normal, but the girls presented the following peculiarities as regards their hands and feet. Each child had six digits on both hands, the additional digit being situated on the ulnar side, and in the case of the three eldest having bony union with the rest of the hand; while in the two youngest the additional finger was attached by a pedicle of skin and vessels as in Dr. Attlee's case. The mother had had the sixth fingers removed from the first and second girls, but on account of her delicacy the hands of the third had not been operated on and I was thus able to see the extra members. On the right hand the finger possessed a metacarpal bone which was in relation with the carpus, but on the left side the digit was very rudimentary, though having bony connexion with the ulnar side of the little finger. The pedunculated sixth fingers of the fourth and fifth girls were removed after ligaturing their pedicles. The middle and ring fingers of the eldest girl's left hand were also webbed throughout their entire length. Their feet showed even greater variation. The eldest girl had six toes on her left but only five on her right foot, with webbing of the great, second, and third toes of both feet. The second had five toes, with slight webbing of the second and third on each foot. The third had six, with the second and third completely webbed on each foot. The fourth girl presented the greatest abnormality of any, having an apparently spatulate condition of each great toe, which on closer examination gave the appearance of a fusion of two separate toes, while in addition to this on the right foot there were two little toes apparently in relation with the fifth metatarsal, the remaining digits of the left foot being normal. The only abnormality of the feet of the newly-born fifth girl was a very slight degree of webbing of the second and third toes of each side. The father of these children had six digits on each hand and foot, with bilateral webbing of the second and third toes. He was an only child and his father and mother were quite normal as regards their hands and feet. He was not related to his wife prior to their marriage.

This remarkable case is another example of the well-established fact of the hereditary tendency of this sort of deformity, and it is noticeable that the male children should have escaped.

Streatham, S.W.

NOTE ON A CASE OF BELLADONNA POISONING.

BY H. JEAFFRESON BREWER, L.R.C.P. LOND., M.R.C.S. ENG.

IT is said that children are able to take belladonna well and do not suffer from any toxic effects, and on looking through Woodman and Tidy's "Toxicology" the only cases of poisoning in children were caused by taking large quantities of the berries. From this point of view I think the following case of what was obviously belladonna poisoning may be of interest.

To a boy, aged four years and three months, suffering from whooping cough, I prescribed two minims of tincture of belladonna and two grains of bromide of potassium, to be taken every four hours. Within half an hour of the administration of the first dose, the mother told me, a red flush came out round the child's neck and on his chest. The mouth seemed dried up and the child was slightly delirious, but in about an hour he got much better. A second dose of the mixture was given four hours after the first, and again in half an hour the child suffered in the same way and was violently sick. Then I was sent for. On arrival I found the child almost covered with a scarlatiniform rash, chiefly on the neck and chest; the pulse was rapid (120) and very feeble; the mouth was dry; the pupils were fully dilated, a narrow ring of the iris only being visible; and the temperature was slightly raised (100° F.). The child was only semi-conscious and was with difficulty roused and could not speak. On administering brandy consciousness and speech returned, the pulse slowed, and the pupils began to contract. When I saw the child on the next morning he had quite recovered, except for a very faint rash which entirely disappeared within 24 hours.

Considering the very small dose administered I think this idiosyncrasy worth recording.

Dalston, N.E.

NOTE ON THE EFFECTS OF BORAX ON INFANTS.

BY JAMES CHARLES MCWALTER, M.D. BRUX., L.R.C.S. IREL., D.P.H.

THE question of the propriety of employing borax or other compounds as a preservative for milk or other foods is one which cannot be decided by the mere *obiter dicta* of the medical man. Powerful commercial influences are concerned in the use of preservatives in food and it is not sufficient for a medical man absolutely to condemn the practice if he finds himself in the witness box under the examination of an able King's counsel. This gentlemen will doubtless demand specific instances of the harmful effects, either from the witness's experiences or from credible works. These instances seem to be particularly scanty in British journals, although Dr. Wyley has done a lot of work on the subject in America. I wish, then, to record a case of chronic borax poisoning which is just now under my care and which seems as conclusive of the evil effects of the drug as a single instance can possibly be, for in this case the mother suckled the infant all the time and gave it no other nourishment.

The infant was two months old when I saw it and had been born a strong, healthy child. A fortnight after birth it developed thrush, for which borax and honey were applied. The child seemed to be relieved of the thrush by this remedy and developed such a liking for it that it was applied most liberally—from two to three four-drachm boxes having been used every week from the second to the eighth week. During this time a progressive wasting had set in, and when I saw the infant there was a marked erythematous eruption on the palmar aspect of the hands and on the plantar aspect of the feet, with distinct desquamation between the toes and the fingers; well-marked urticarial eruption was present on the arms and forearms, but the region between the legs was notably free from eruption. There were tumefaction and tenderness of the abdomen, and a raw, pinky redness of the lips, tongue, palate, and throat, with vomiting and looseness of the bowels. The face had a wizened look, the skin was soft and brownish, the eyes were bright, and the joints, especially the knees, tender, swollen, and somewhat stiff. There was no evidence of syphilis or other cause for the wasting and rash except the borax, of which the child had about ten grains every day for six weeks. On stopping the borax and confining the infant to the breast milk, together with a little raw beef-juice, it appears to be recovering rapidly.

"MINER'S PHTHISIS."—At a recent meeting of the Redruth (Cornwall) board of guardians the Local Government Board inspector (Mr. J Preston Thomas) referred to "miner's phthisis" and its effect on the pauperism of the union. He mentioned that nearly 350 cases of pauperism were due directly to this disease, or about one-quarter of the whole pauperism in the Redruth union.

Dr. INGLIS PARSONS seconded Dr. McCann's proposal, but he thought that the public also must be educated, and that it was no good educating practitioners, midwives, and so on, if the patients would not consult them.

Dr. WILSON said that he did not think that practitioners were often clever enough to diagnose early cancer even if they did examine. In his part of the country he had noticed that 50 per cent. of the cases had not been examined at all, and that of the remaining 50 per cent., 25 per cent. had not been diagnosed. He therefore thought the great thing was to instruct the practitioner. As an example of what instruction might do he might say that whereas the average number of operable cases coming under his notice up to 18 months ago had been gradually rising from 14 per cent. to 16 per cent.; during the last 18 months since he had read a paper before the local medical society on the early recognition of cancer the percentage had risen to 30. He also instructed nurses and midwives in his lectures, but did not think that leaflets should be sent out to the general public.

Dr. MUNRO KERR pointed out that the proportion of operable cases was higher when associated with pregnancy and opined that the cause of this was due to the more frequent examinations that were made in women during pregnancy, labour, and the puerperium. He thought a large number of women did not apply for advice because they were frightened of being told that they had cancer.

Dr. JOHNSTONE regarded bleeding and discharge as late signs of cancer and not early as generally given in the text-books. He did not know about the early stages here, and it should be remembered that in many cases the gynæcologist was unable to diagnose the disease before it had become inoperable. He thought that it was a good thing to alarm the medical profession, and it was not necessary that any general practitioner should be able to diagnose cancer of the uterus so much as that when any symptoms or signs arose he did not understand he should send the case for further advice.

Dr. EDGE said that if any leaflet were sent out the greatest possible care must be taken with its phraseology. Many patients did not care to be examined because they were afraid of being laughed at by the medical attendant, so that they put up with slight symptoms. The opportunity for examination should be made so easy by having female gynæcologists in different centres that women would go to them for the least trouble. Dr. Edge thought that no woman should be given the certificate of the Central Midwives Board unless it could be proved that she was able to insert a speculum into the vagina, expose the cervix, and tell whether its appearance was normal or otherwise. They might be accused that all these precautions were being advocated to benefit medical men pecuniarily, but no one made such a suggestion against dentists who advised the periodical examination of the teeth.

Dr. JOHN GILCHRIST (Glasgow) pointed out that no allusion had been made to the utility of physiological research in these cases. He thought the profession was influenced by a morphological bias. Before cancer made its appearance some physiological changes took place in the body; for instance, it had been noted in France that long before the appearance of cancer a marked inhibition in the secretion of urea took place.

Mr. CHARLES RYALL (London) said that it was known that highly satisfactory results followed radical treatment in the early stages. The anatomical position of the cervix and the free communication between its fundus and the vagina made carcinoma of this organ almost an external growth and the surgeon saw the majority of cases only when the disease was too far advanced for radical operation in spite of this fact. Of the last 100 cases of uterine cancer under his care at the Cancer Hospital, in only 24 was he able to attempt to remove the disease in spite of an extensive abdominal operation. The duration of the symptoms in the operable cases varied from hæmorrhage of one month's duration in one case to three years in two other cases. Among the 24 cases 15 had symptoms for six months or less, ten of these being for three months or under, while six had symptoms of from one to three years, all of the last class being in women who had passed the menopause. The cause of delay in seeking advice was in most cases ignorance. The public regarded cancer as an incurable disease accompanied by pain, and pain being regarded as the principal symptom the first sign, hæmorrhage, was disregarded, so that by the time pain had appeared the case was inoperable. The medical practitioner was also to blame in many cases and in several cases that had come under his observation no proper examination had been made. As a remedy he suggested (1) improvement in the teaching of the student and (2) education of the public in regard to the symptoms.

Dr. CAMERON thought that one reason why the public did not seek relief sooner was due to the fact that they considered pain to accompany disease in all cases, whereas it was a late symptom in carcinoma of the cervix. He advised (1) more thorough instruction of the students; (2) instructions to nurses and midwives in the symptoms of the disease; and (3) that central laboratories should be established to which practitioners could send curettings for examination by a skilled cancer pathologist. He maintained that there were two great classes of operative cases: (1) cases in which a cure might result and (2) cases in which operation was undertaken to relieve the patient of her distressing symptoms and make her closing stages more comfortable.

Dr. G. RICE (Derby) said that in his part of the country for years the cases had been sent to hospital by practitioners but since the passing of the Midwives Act a large number of people had passed out of the practitioners' hands for their confinement and had gone to midwives and that it was this class, therefore, that it was now necessary to instruct. The Central Midwives Board should be asked to see that a knowledge of the early signs of cancer was included in the schedule for examination. He also thought that midwives should be trained longer; whilst in Germany the training took three years here it took three months.

The PRESIDENT of the section was of the opinion that every nurse and midwife and most lay women knew that the early signs of cancer were bleeding and a discharge. The fault of early recognition of these cases was due to the medical attendant not being able to diagnose them. Many of them refrained from making vaginal examinations because they had no confidence that they would be able to make any diagnosis when they had. This state of affairs would never be remedied until the student was compelled to devote a larger portion of his curriculum to the study of obstetrics and gynæcology. Every medical student should attend an obstetrical and gynæcological hospital for six months and by the rules of the Irish colleges they had to, but the thing was a farce. There was no rule to make them attend so many times a week or be signed up by their teachers and a large number when they had attended 14 days and finished their cases did not go near the place again. He did not believe much in the idea of sending out pamphlets.

The PRESIDENT then put the following motion to the meeting, which had been proposed by Dr. McCANN and seconded by Dr. INGLIS PARSONS:—

> That a committee of this section be formed to consider what steps may be taken to disseminate a knowledge of the early signs and symptoms of cancer of the uterus.

An amendment to this was proposed by Dr. WILSON, seconded by Dr. SPENCER, and carried *nemine contradicente*:—

> That the Council of the British Medical Association be requested to appoint a committee to consider the best means of disseminating knowledge of the importance of the early recognition of uterine cancer.

This was then put as a substantive motion and was carried and the meeting terminated.

PSYCHOLOGICAL MEDICINE.

WEDNESDAY, JULY 31ST.

The proceedings commenced with

The Presidential Address,

delivered by Dr. T. CLAYE SHAW (London). He acknowledged the honour of being appointed president of the section and felt the responsibility of the office, which, however, he accepted with pride and gratification. The importance of these meetings must be regarded as milestones of progress and as a record of the relation of the specialty at a definite period. Their attitude of to-day was one of expectant attention, that their *support* and foundation was deeply fixed on the *common* bedrock of vital bodily processes, and that they really pulsated with all the vibrations of the medical system. This made them confident that so long as they were true to their conditions in their relations with the medical and social environment they must continue to stimulating and not seldom beautiful in their expression, as witness his chapter "After Death," which is a veritable prose poem, even though, as some may think, it is "too good to be true." In this and other parts of the book the ultimate destiny of man is set upon a plane that almost transcends intellectual comprehension, but in such chapters as that in which he makes out a powerful case for the deterministic view of life and at the same time demonstrates that it is not really incompatible with the doctrine of moral responsibility he succeeds notably in unfolding highly philosophic concepts in a way to be understood clearly by readers not trained in such subtleties. Perhaps the most original hypothesis is that in which he seeks to explain the Existence of Evil; the thesis is closely reasoned and far more satisfying than many more orthodox explanations and his treatment of evil as a valuable evolutionary force, if less original, is as well expressed. The chapters on Right and Wrong and the Sanction of Morality fall into line with current rationalistic thought, but the author is always careful to insist that the discovery of the machinery by which such ends are wrought should only serve to strengthen the faith in the inflexible divine purpose acting through such means.

Those who enjoy the full faith in "revealed religion" will, if they read Mr. Pearson's book, doubtless disagree with some of his conclusions, but they cannot quarrel with the moderation with which he states his case; and to many who are seeking in vain an answer to the eternal question, "What is Truth?" his pages will present a scheme of philosophy that may well satisfy their intellect and at the same time afford them the basis of a real and helpful "Natural Religion."

The Children of the Nation: How their Health and Vigour should be Promoted by the State. By the Right Hon. Sir JOHN E. GORST. London: Methuen and Co. 1907. Pp. 297. Price 7*s.* 6*d.* net.

THIS volume is evidently to be taken not as a standard contribution to sociological literature but as an attempt to open the eyes of educated and thoughtful people to the many and terrible causes of degeneracy that are at work amongst the children of the poorer classes and to suggest some means for their remedy. Its publication was some months ahead of the present International Congress in School Hygiene and it can be recommended to the attention of all who are interested in the success of the objects for which that Congress is convened. As such the book deserves wide recognition, for it contains much food for reflection. The argument hangs practically on these two texts, the one quoted from a working man. "There are some folks whom society has got to pay for either at the beginning or end of their lives, and it is much cheaper to pay at the beginning"; the other the author's own dictum: "The child is worth a great deal too much to be used for improving the moral character of the parent." In other words, if the State finds a starving child its duty is to feed him, even at the risk of undermining the parents' sense of responsibility, with which pious opinion few will cavil. The very vexed question of the universal State feeding of school children Sir John Gorst discusses fully, and approves the provision of a nourishing dietary at the public expense in the case of destitute children and at the parents' expense where they can afford it. He points out fully the delinquencies of boards of guardians in shirking their plain duty of feeding starving children under the present law and also in evading the responsibilities of providing free medical treatment for poor people by the means of casting discredit on even worthy applicants for such relief. The need of medical supervision of the conditions of child life and education, including routine physical examination of all elementary school children, is warmly advocated, and also the advantages of properly supervised crèches, as well for their value as domestic training schools for girls over 15 years of age as for their advantages to mothers and children. The common diseases of children, hereditary and acquired, are touched on and the common-sense remedies for them are pointed out; the most radical step suggested is the protracted segregation in hospitals of persons suffering from syphilis. The vital questions of infant mortality and infant feeding receive fairly adequate attention; these problems cannot be forced too insistently on the public. The present conditions of child employment are criticised with full knowledge. The author goes wide of his subject on several points but the reader who knows nothing of the admirable system of compulsory insurance against sickness and old age that was Bismarck's splendid legacy to the working classes in Germany will forgive this digression. The account of the Forest School at Charlottenburg, where ailing children are tended and taught, forms another severe object-lesson from the same country. The indictment of our local authorities for their supineness in administering the existing public health enactments includes a statement that will surprise many—viz., that it is within the power of any local authority to build and to administer a general hospital for the public use out of public money.

Sir John Gorst claims that free medical treatment of the working classes would be no more socialistic a measure than is the present provision of free hospitals for infective diseases, but he does not suggest a means of finding the money to pay the medical men, and in his account of the friendly societies we could have wished for a mention of the inequitable terms of remuneration which they afford to our profession. On the whole the work leaves a feeling of dissatisfaction at the position of England in this great matter of child-rearing as compared with other civilised countries.

Theories of Chemistry. By SVANTE ARRHENIUS. Edited by T. SLATER PRICE, D.Sc., Ph.D., F.I.C. London: Longmans, Green, and Co. 1907. Pp. 212. Price 5*s.* 6*d.* net.

THE name of Svante Arrhenius, the distinguished director of the Nobel Institute, Stockholm, is honoured by chemists of all nations as belonging to one who has enriched very considerably our knowledge of the nature of solution. To him we owe largely the development of the theory of ionic dissociation, a theory which has placed many physiological phenomena in a new and important light. His researches led him to suppose that chemically active molecules are identical with electrically active ones, and therefore that the conductivity of an acid was to be regarded as a measure of its strength. Ostwald, another brilliant investigator in the same field, tested this speculation with the result that he pronounced Arrhenius's view to be in fact a law. Finally, the subject was pursued further with most fruitful results which culminated in the formulation of general laws for dissolved substances. The application of these laws in plant and human physiology is of the utmost interest. The power possessed by plant cells of sucking in pure water from a surrounding weak salt solution is a case in point. When the solution reaches a certain concentration equilibrium is established and no water enters into the cells; the solution and the cell-content are then said to be "isotonic." If the solution is still more concentrated water passes from the cells to the solution, and the protoplasm contracts and does not fill out the surrounding cell-wall. Similarly, the red blood corpuscles behave like the plant cell. When the solution surrounding the red blood corpuscles is too weak they give up their colouring matter or hæmoglobin to the solution. When the solution is too strong the corpuscles shrink and sink to the bottom.

Cross Hospital the notes of the necropsies upon 1099 adult cases gave 85, or 7·7 per cent., cases of cirrhotic liver. At Claybury Asylum the notes of 1271 necropsies were investigated and there were only 23 cases, or 1·8 per cent., of hepatic cirrhosis. Dr. Mott agreed with Dr. W. C. Sullivan and Mr. W. Bevan-Lewis that alcohol as an efficient cause of insanity was nothing like so great as the published reports of the Commissioners in Lunacy indicated. Inland and agricultural communities were the least inebriate but had the highest ratio of pauperism and insanity, while maritime, mining, and manufacturing communities were the most intemperate and revealed the lowest ratios of pauperism and insanity. Dr. Mott proceeded to discuss the action of alcohol on different individuals, and pointed out its effect on the business man of ordinary mental stability who on account of his occupation became the victim of the vicious habit of indulgence to excess. That alcohol inflamed the emotions, converting anger into fury and fear into despair, thus leading to homicidal and suicidal tendencies and crimes of a sexual character. He remarked that often alcoholics were skilled workmen and artists, the result of actions becoming subconscious and habitual by constant repetition. The æsthetic feeling which was last to come evolutionally, therefore normally the first to go, might, owing to its constant activities in associated memory, *persist* when the moral sense had gone. It was sometimes urged that artistic geniuses used alcohol in excess, and that their æsthetic feelings and passions had been given full play without restraint. But poets were born and not made and their imagination persisted in spite of alcohol. Dr. Mott showed on the screen sections of the cortex of normal brain, the brain of a case of polyneuritic psychosis, and of a case of acute general paralysis. He discussed the predominant features of the varieties of mental derangement associated with alcoholism. He stated that if hallucinations and delusions persisted whilst the mind otherwise became clear it was probable that alcohol only played a subordinate part. The patient might be depressed or excited according to his temperament. The majority of cases who either did not recover speedily or not at all exhibited signs of depression and frequently they drank because they were miserable and had troubles. To ascertain whether alcohol was the essential cause of insanity it was desirable to look for those characteristic signs of alcohol poisoning found in delirium tremens and polyneuritic psychosis. In conclusion, he called attention to the effects of alcohol in the spread of venereal disease. Syphilis was often acquired as a consequence of alcoholic intoxication. It was noteworthy that intemperate women were frequently sterile or had a high birth-rate and a high death-rate. He considered alcohol and venereal disease allies in destroying the offspring of those who were unable to drink in moderation. He maintained that while syphilis and drunkenness were, continually destroying neuropathic stocks they were also continually producing them, for the surviving offspring much more frequently developed neuroses and psychoses than the offspring of healthy parents. How far alcohol acted in tempting the weak-minded to destruction, whilst the strong-minded persisted, was a matter of speculation. Those nations that had drunk alcohol for ages past were of greater brain power, though not of better bodily physique than the Mahommedans who took no alcohol.

Dr. C. MERCIER (London) felt that our previous ideas as to alcohol producing insanity were no longer tenable. He had always insisted that the influence of the personality of the individual was all-important. The same doses administered over the same time produced entirely different results. As visitor to Aylesbury Reformatory for Inebriates he had experience of habitual drunkards of pronounced character. It was not the amount taken but the little that had effect, He felt we were more temperate than formerly and there was no need to be pessimistic as to the future of the English race. He considered that many cases of insanity were due to syphilis in ancestors which affected remote offspring.

Dr. E. W. WHITE (London) commented on the rareness of cirrhosis of the liver met with in asylums. He had only met with about six cases in 33 years. He regarded alcoholism often as an early symptom of insanity and that statistics had but little value.

Dr. P. W. MACDONALD (Dorchester) was glad to find Dr. Mott supporting his views expressed in his recent address as President of the Medico-Psychological Association. He emphasised the fact that in districts where there was a high ratio of insanity to the population there was a low ratio as to alcoholism, and that the converse also held good.

Mr. HERBERT G. SHORE (Newquay) expressed appreciation of Dr. Mott's paper and commented on some of the remarks of Dr. Mercier.

Dr. H. M. HURD (Baltimore) stated that in examining large institutions for the insane he could not find alcohol as a cause of insanity in more than from 5 to 10 per cent. of cases.

Dr. F. PETERSON (New York) concurred in the fallacies derivable from statistics. He cited the alcohol test used in Germany for differentiating pathological from normal drunkenness. He considered that alcohol weeded out degenerates, although the process was a slow one.

Professor W. D. HALLIBURTON (London) spoke of alcohol from the physiological standpoint. He regretted the attitude taken by total abstainers, which was against all common sense.

Professor R. J. ANDERSON (Galway) spoke of the different effect of alcohol on the mucous membrane of the stomach in various people and believed that the most beneficial narcotic effects occurred in cases of brain and muscle fag.

Dr. A. T. SCHOFIELD (London) mentioned that all total abstainers were people of pronounced and extreme views.

Dr. G. M. ROBERTSON (Larbert) still regarded alcohol as the most important single factor in the causation of insanity in men.

Dr. D. YELLOWLEES (Glasgow) did not wish to glorify the use of alcohol and regarded it rather as a bane than a blessing to mankind. He cited the case of a child begotten by a father in a state of alcoholism which led to the parent reforming his habits ever afterwards.

Mr. A. N. DAVIS (Exminster) stated that in the county of Devon the alcoholic cases were admitted to the asylum chiefly from Devonport where the wages were higher.

Dr. W. F. MENZIES (Cheddleton) spoke of the use of the terms "epicritic" and "protopathic" as applied to the two types of alcoholism.

Dr. F. W. EDRIDGE-GREEN (Hendon) stated that in his practice he found bromides and alcohol as most useful therapeutic agents.

Dr. L. R. OSWALD (Glasgow) said that alcoholism and weak-mindedness were more prevalent in those parishes of Glasgow where public-houses were most numerous.

Dr. T. W. MCDOWALL (Newcastle) regarded Northumberland as one of the most drunken counties in England and it also had a greater proportion of criminality, yet there was a smaller percentage of insane to sane of the population.

The PRESIDENT summed up the discussion and admitted that though they might do without alcohol, yet there were occasions when it would appear certainly to have saved life.

Dr. MOTT replied to the various speakers and referred to certain statistics of abstainers sent to asylums and also mentioned some recent experiments by Dr. W. H. Rivers of Cambridge combating the view generally held of the baneful influence of alcohol in mental fatigue. He considered that people of real civic worth were able to work and to work well with the moderate use of alcohol.

THURSDAY, AUGUST 1ST.

In a paper on

Three Cases of Periodic Dementia,

read by Dr. MERCIER, he said that the term "dementia" was used in two entirely different senses. It was used to express the condition of permanent damage of brain and consequent defect of mind and conduct: in fact, those examples of human wreckage that constituted the bulk of inmates of asylums. But it did not include all the hopelessly insane. Those who exhibited active symptoms and those with delusions were called chronic mania or paranoia. A chronic maniac, however, who had long periods of quietude and short periods of excitement was a dement. But dementia had another meaning. When it included cases deprived of mind only temporarily it would appear that the term "anoia" would be more suitable for such conditions had not this term been otherwise applied. Dementia as a rule was used to connote a deep dissolution of mind. But every case of insanity might be regarded as a case of dementia. Loss of control revealed dementia; that which was taken away allowed the remainder to act disorderly. The following three cases agreed in the periodical removal of the higher faculties of mind. The first case was that of an anæmic girl, aged 17 years, who was childish for her age, and who had not yet menstruated. Every two or three months she became "dull in her head"

Roman times and also mentions the most important early Arabic works.[2]

Before proceeding to describe the instruments themselves a chapter is devoted to the materials of which they were made, which most frequently was bronze. Iron was commencing to be used for them in the age of Hippocrates who speaks of cauteries being made of it. Iron instruments, however, of all kinds have necessarily almost invariably perished by oxidation and so it is not surprising that of the innumerable cauteries that must have existed few are ever found, though some made of copper and some of brass have survived. Two scalpels from Pompeii are of the latter metal, containing 25 per cent. of zinc. Leaden sounds and tubes for intrauterine medication are spoken of by Hippocrates, or in writings of his school, and later authors refer to leaden tubes for insertion in the rectum and vagina to prevent cicatricial contractions and adhesions after operations. Gold was also used; Priscianus advised it for cauteries for stopping hæmorrhage of the throat and Hippocrates used it as a dental support in an operation necessitated by fracture of the jaw. The Athens Museum possesses a forceps of silver and others are known of this metal. Hippocrates describes a uterine syringe with a silver tube and Albucasis mentions silver catheters.

The chief sites of the discovery of ancient medical instruments have been Pompeii and Herculaneum. In the former city a physician's house and at least two chemists' shops have been excavated. Another large find was at a Roman military hospital at Baden. It contained 14 rooms and a colonnaded portico for the patients. Sporadic relics are those contained in the tombs of medical men. One such collection may be seen in the Museum at Namur. The instruments discovered find their way into various museums and Dr. Milne gives a list of these, but appears to be unaware of the magnificent collection accumulated by Dr. Deneffe which is stored in the École du Génie Civil, Rue Plateau, Ghent.[3]

Dr. Milne commences his account of the instruments, of which examples are known, with the knives, and ten of the plates are occupied with specimens of various kinds. A common practice was to make one end of the instrument into a weapon of another kind; thus many knives are united to a scalpel, whilst some lithotomy knives have a hook at the other extremity to extract the stone after the perineal incision was made. Chapter IV. is devoted to the probes; these frequently had a spatula at the other end. Several bifurcated probes are shown but no example of a three-pronged one is known which the Aldine edition of Celsus makes him mention. The chapter upon ancient forceps follows and describes those for epilation, the polypus forceps, and the vulsellum, and those for the uvula, and the pharyngeal forceps, and illustrations of all are given. The accounts of bleeding cups, clysters, and bone and tooth instruments are very complete. The *βελουλκόν*, a kind of forceps for extracting the points of weapons from wounds, is described from Paulus Ægineta and then illustrated by the fresco of Æneas wounded, found in a house at Stabiæ, where Iapix the surgeon is withdrawing the weapon by means of a long forceps with crossed levers. The chapter upon gynæcological instruments is of much interest. The question is debated as to whether the Greeks and Romans ever had an instrument for extracting the child alive and that is decided in the negative. Of course, some of the traction hooks and toothed forceps may have withdrawn the infant mutilated but living. The bibliography does not mention the great French "Dictionary of Greek and Roman Antiquities," by Daremberg and Saglio, published by Hachette et Cie, in which much information on the subject will be found, but the omissions in the work are few; it is a most useful survey of the subject and we hope a second edition will soon be required and that it will be translated into other European languages.

LIBRARY TABLE.

Catholic Churchmen in Science. By JAMES J. WALSH, M.D., LL.D. Philadelphia: The Dolphin Press. 1907. Pp. 221. $1 net.—Dr. Walsh has collected a series of short sketches of the lives of Catholic ecclesiastics who have laid foundation-stones in different branches of science with the expressed intention of refuting the oft-heard contention that between the scientific and religious minds there is an impassable gulf fixed. No unbiassed reader of his book can deny that he has well fulfilled his purpose; indeed, a capitulation of his chapters would be sufficiently convincing to anyone even slightly acquainted with the history of science, for they include the honoured names of Copernicus, Basil Valentine the chemist, our own Linacre, Father Kircher, S.J., Bishop Stensen, anatomist and geologist, Abbé Haüy, the first crystallographer, and lastly, a name that succeeding generations will hail as one of the foremost pioneers of biological science, Abbé Mendel. That great and unassuming man's splendid research in heredity conducted during patient years in his monastery garden at one time, with a display of religious zeal that brought about his election as abbot is incontrovertible proof of the author's thesis. A lucid epitome of his work is given and that of the other masters of science is as well summed up. All English medical men should at least know something of Linacre, fellow and peer of Erasmus and Colet and pious founder of our College of Physicians; it will be news to many that in later life the religious life led him to abjure his well-earned worldly honours. Whilst in sympathy with nearly all of Dr. Walsh's claims we can scarcely pass unchallenged his ingenious suggestion that Galileo's persecution was brought on himself by his irritating habit of upholding his opinions over-strenuously and inopportunely; had he never spoken of anything else his message should surely have excused him those epithets! The omission of Roger Bacon from the list of great scientific ecclesiastics is a little surprising.

Materia Medica. By W. HALE WHITE, M.D. Lond., F.R.C.P. Lond. Tenth edition. London: J. and A. Churchill. 1907. Pp. 692. Price 6*s.* 6*d.*—When a book has reached its tenth edition there is but little to say about it. Dr. Hale White's work treats, in addition to Materia Medica, of Pharmacy, Pharmacology, and Therapeutics. It is one of the best of the smaller treatises upon the subjects in question. We would suggest that in the next edition the warning rightly given under the head of Strychnine as to its incompatibility with the bromides and the iodides should be repeated in the list of incompatibles given under the heading of the two last-mentioned preparations. A combination of a bromide with a strychnine-containing preparation is both useful and commonly prescribed, but the two drugs should always be administered separately. In this way there is no danger of strychnine poisoning occurring.

Synopsis of the British Pharmacopœia, 1898. By H. WIPPELL GADD. Sixth edition. London: Baillière, Tindall, and Cox. 1907. Pp. 227. Price 1*s.* net.—This is a useful little book, as it gives in a handy form the mass of details contained within the pages of the British Pharmacopœia. In addition to the synopsis the present edition contains the poison laws for both Great Britain and Ireland. In one respect at least the Irish schedule is superior to the one for Great Britain, for in Ireland phosphorus and all preparations to the hæmoprotozoa. To this group were referred the hæmogregarines, the plasmodidæ, the schaudinnidæ (Sambon), which included the spirochætæ, the leucocytozoons, and treponema, and lastly the hæmoproteidæ, including the Leishman-Donovan bodies, the trypanosomes and babesia.

---

[2] The new inscriptions, found at Ephesus, recording the acquisition of prizes by successful medical students, who wrote theses upon special subjects, mentions a class whose monographs were devoted to surgical instruments both those already known and suggestions for new ones.

[3] The curator is M. von Hammer, 49, Rue van Hulthem.

Professor W. J. R. Simpson (London) opened a discussion on the

Best Methods of Carrying out Anti-malarial Sanitation, with Special Reference to such Plans as may be Most Suitable for Populations in the More Primitive Stages of Civilisation.

He reviewed the various methods of anti-malarial sanitation and showed the efficacy of drainage as illustrated in India, Port Swettenham, and Klang. He insisted that different conditions demanded different modes of applying anti-malarial sanitation. He notified the artificial conditions favouring malaria, and especially insisted upon controlling engineers and contractors while carrying out public works in malaria districts. He cited the American method of preventing disease by the systematic application of hygienic measures as one well worthy of imitation.

Professor Hans Ziemann (Cameroons, West Africa) read a paper on the

Prevention of Malaria in Uncultivated Districts.

He stated that they could practise general malarial prevention (1) by extirpating the parasites in man by (*a*) quinine prophylaxis of those infected with malaria, and (*b*) by killing the parasites which invaded man at the beginning of their development and before a fever attack had set in (i.e., real quinine prophylaxis); (2) by extirpating the mosquitoes which conveyed malaria; (3) by protecting man against the bites of malaria mosquitoes; and (4) by endeavouring to raise the resisting power of malaria-infected people by social prophylaxis, by better feeding, housing, clothing, and by instruction of the nature of malaria to the general public. He contended that an absolute protection against malaria, that was, against the first infection, was not to be effected by quinine alone, and one must endeavour with the smallest possible doses of quinine to afford what protection was possible.

Major A. H. Nott, I.M.S., related his experience in Murshedabad, India, of a campaign against malaria by preventing mosquito breeding in the neighbourhood of dwellings.

Dr. W. T. Prout, C.M.G. (Liverpool), stated that it was essential that the medical officers in West Africa must have more executive powers granted them if real progress was to be made in the elimination of disease in West African colonies.

Dr. H. Marcus Fernando (Ceylon) described the difficulties of the application of anti-malarial measures in Ceylon.

Dr. Andrew Balfour (Khartoum) said that malarial sanitation in the Sudan was becoming more difficult owing to the increase in area of cultivation by irrigation due to the increased size of farms owned by capitalists taking the place of small holdings. It was satisfactory, however, to note that legislation had been introduced for the regulation of the irrigation channels whereby they could be emptied systematically owing to their being placed on a higher level than the surrounding fields, and that leakage and accumulation of pools of water in the channels were prevented. Rice cultivation, moreover, was kept at a distance (one mile) from the neighbourhood of the town or village.

Dr. Louis W. Sambon (London) considered that almost all practised methods of malaria extinction were apt to be temporary merely and that some more thorough and permanent method of dealing with the matter required to be introduced. They had examples of the disappearance of malaria from England and Holland and many other places in Europe and India, the explanation of which was to be found in hyperparasitism; Ross's black spores were a hyperparasite which attacked the malaria organism within the stomach of the mosquito and destroyed it.

Major G. T. Birdwood, I.M.S., pointed out the conflict between the economic and commercial aspects of malaria extermination and considered drainage to be the chief means to hand.

Sir Patrick Manson insisted upon the importance of educating the children in native schools in elementary hygiene and considered that it was also necessary for medical men to cease calling officials fools because they did not fall in with their ways of thinking. The rôle of the medical man was to teach the meaning of recent investigation in regard to the elimination of disease to all and sundry who came within his sphere of action. Sir Patrick Manson also upheld the necessity for further investigation, especially in the endeavour to find out the explanation of the absence of malaria in certain districts, in order to imitate the conditions in infected areas.

Lieutenant-Colonel G. M. J. Giles, I.M.S., considered that too much attention should not be devoted to the differentiation of mosq[illegible]uitoes when malaria was rife in any district but that all mosq[illegible]uitoes should be exterminated. The habits of mosquitoes [illegible]aried in different places: some thrive in fresh water, some [illegible] in brackish water, and some in salt water, were the condition[illegible]s of life of these mosquitoes better known the question of mos[illegible]quito extermination, at any rate in cas[illegible] towns, could be more [illegible] scientifically dealt with.

Major Leonard R[illegible]ogers, I.M.S., gave a Lantern Demonstration of tempe[illegible]rature charts illustrating the course in various Indian fevers, [illegible]ncluding malarial fevers, [illegible] fever, three-day fever, typ[illegible]hoid fever, and kala azar.

DISEASES OF C[illegible]HILDREN.

WEDNESDAY, JUL[illegible]Y, 31ST.

After some brief remarks by the [illegible] PRESIDENT, Mr. A. H. Tubby (London), outlining the busines[illegible] before the [illegible], Mr. D'Arcy Power (London) opened [illegible] a discussion on

The Diseases and Displacements of [illegible] *the Te*[illegible]

He grouped the subject under the head[illegible] syphilis, malignant disease, innocent tumours [illegible]e of [illegible] The displacements, he said, were due to faul[illegible] the [illegible] development. In regard to tubercle, most [illegible] testicles seen in very young children in the out[illegible] in [illegible] at hospitals were due to tubercle growing in [illegible] had been prepared for infection by changes due [illegible] syphilis. He asked whether it was certain tha[illegible] an [illegible] inflammation of the testicle ended in atrophy an[illegible]es [illegible] suffering from this form of disease were more o[illegible] to become the subjects of spinal caries. Syphi[illegible]mber [illegible] mation of the testicle was commoner in young c[illegible]nd it [illegible] tuberculous orchitis and the tunica vaginalis was so[illegible] was a [illegible] involved that a hydrocele was of almost constant [illegible] Absence of pain caused the condition to be overloo[illegible]tted [illegible] majority. Wasting of the testis was a frequent con[illegible] were [illegible] Were there any observations as to retardation o[illegible] consequent on this atrophy? Teratomata were due [illegible] to dermoids or sebaceous tumours. Sarcoma of the [illegible] stood in need of further investigation in the ligh[illegible]t of Foulerton's recent work. Was it not possible that [illegible] the cases grouped as sarcoma were in reality exa[illegible] carcinoma? Mr. Power was not satisfied with the [illegible] of orchidopexy in cases of undescended testis an[illegible] advised removal of the testicle in nearly every case wh[illegible] organ was retained in such a position that it was expo[illegible] injury, especially if there was evidence of a hernia. [illegible] no hernia was present he advised the parents to wait ti[illegible] child was seven or eight years old in the hope tha[illegible] testicle might descend into the scrotum as the child g[illegible] He asked opinions on the following points. First, as t[illegible] indication for operating when the testicle lay at or [illegible] the external abdominal ring; secondly, as to the ad[illegible] which should be given when both testicles were [illegible] descended; and, thirdly, as to the most appropriate t[illegible] for operating when there was no hernia. He also allu[illegible] to the treatment of ectopic testicle, and finally pointed [illegible] the frequency with which hydrocele occurred in childre[illegible] the ease with which an erroneous diagnosis was made, an[illegible] the means by which such mistakes were best avoided.

Mr. Russell J. Howard (London) said that torsion occurred both in the fully and in the imperfectly descended testicle and in 11 cases recently collected by him the accident was about equally divided between the two conditions. Of the undescended ones four were in the inguinal canal and one had been replaced in the abdomen; the ages of the patients extended from four months to 24 years. Such causes as could be ascertained were violent exertion, straining, misapplied taxis, and suddenly crossing the legs, but in two instances the accident occurred while the patient was asleep in bed. The symptoms somewhat resembled those of strangulated hernia but vomiting was less persistent, flatus escaped, and the bowels reacted to purges or enemata, and there was usually a rise of temperature. The testicle became swollen

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT EXETER.

THE Science and Education Committee of the National Temperance League held its annual breakfast in the Royal Public Rooms at Exeter on the morning of Thursday, August 1st, at which some 160 members of the British Medical Association were present. The Mayor of Exeter, Mr. W. H. Reed, presided, and was supported by, amongst others, Dr. Ransom Pickard (Sheriff of Exeter), Dr. Henry Davy, Dr. R. A. Reeve of Toronto, the Archdeacon of Exeter, Sir John Moore, and Mr. W. McAdam Eccles, who subsequently took the chair on the departure of the Mayor for another engagement. A statement concerning the evolution of scientific temperance was read by the secretary of the league, Mr. John T. Rae, in which he said that while recognising that the medical administration of alcohol in scientific doses as an instrument of precision was one wholly for the determination of the profession, the National Temperance League was convinced that the evils of intemperance could only be thoroughly eradicated by the application of preventive measures to the present and rising generations. With the adult of to-day the issue joined was between abstinence from alcohol and its moderate use. The former was abundantly sustained by the scientific evidence already available and by the daily growing experience of its value in resistance to, and recovery from, disease; the latter displayed lack of knowledge as to the action of small doses of alcohol in producing mental and physical inefficiency. The National Temperance League therefore pleaded for a corrective and confirmative investigation, conducted under thoroughly scientific conditions, of the results of recent research with a view to the enlightenment of the public. The Mayor of Exeter said that he was only too glad to find himself associated with such a proceeding. The subject was one of such great importance that he wondered sometimes that the profession as a whole did not take it up with more vigour and more seriously than it did. Dr. Davy said to his mind the evils of drink which were brought on this country in crime and disease merited the serious attention of every Englishman, and it merited it all the more because there was no question that drink was increasing among the women in England, and if the women of England were going to turn out a drunken lot of mothers who would not look after their children then England was in a very bad way: but yet the hesitation he had in coming there was because most of the temperance societies and a large number of the temperance advocates talked the most unscientific twaddle ever invented. He expressed himself in favour of light beers, giving them a preference over much of the tea which is used as a popular beverage. On the other hand, he emphatically supported the principle of temperance. He never had recommended a patient to take alcoholic drink and never would do so. There was as yet little definitely known concerning alcohol and its effects but the scientific facts which they did know were that alcohol was not a necessity of life and very rarely useful in disease, and that it was not advisable to drink half as much as was done. Dr. Pickard contended that there was a great future in teaching children on temperance lines. He believed that the public, especially among the middle classes, were becoming much more temperate. Dr. Reeve said that the principles which actuated the league had been the guiding principles of his life and he had always been what was known as a total abstainer. He could not refrain from saying that the influence of the medical profession and of the laity at large would be much greater with those who took too much alcohol if they would practise at least moderation in the sister habit of tobacco smoking. Sir John Moore (Dublin) said he thought the drinking of actual alcohol *per se* was not very prevalent in this or any other country. It was the preparations containing alcohol that were taken and with which they had to deal. Alcohol was a most disagreeable thing to take and he did not suppose anybody in their senses would dream of taking alcohol, but he went further and said a great many of the beverages taken by total abstainers contained an appreciable amount of alcohol. It was quite possible to take too much alcohol in ginger ale. As a physician of one of their large Dublin hospitals, his experience was that intemperance in beverages containing alcohol was a most potent factor in the production of disease. He had no hesitation whatever in saying that intemperance led to tuberculosis. A vote of thanks to the Mayor for presiding was proposed by Dr. T. N. Kelynack and seconded by Dr. G. Basil Price, and was responded to by Alderman H. Gadd, J.P., on behalf of the Mayor.

The annual dinner of the Association was held on August 1st under the genial chairmanship of the President, Dr. Davy, in the large hall of the Royal Public Rooms. After the usual loyal toasts had been enthusiastically honoured Mr. Andrew Clark proposed "The Imperial Forces of the Crown," in the course of which he dwelt on the importance of the toast it was his duty and privilege to submit to the audience he addressed. This was replied to by Inspector-General James Porter, R.N. (President of the Naval and Military Section), and by Brigadier-General G. Kirkpatrick. Mr. P. M. Deas was entrusted with the toast of "The Bishop of the Diocese and Clergy of all Denominations," which was eloquently responded to by the Bishop of Crediton. Chancellor J. Edmonds proposed the toast of "The British Medical Association," which was duly acknowledged by the Chairman of Representative Meetings, Dr. J. A. Macdonald. After Sir John Moore had given "The Health of the President," which was drunk with great enthusiasm, the dinner concluded with the toast of "The Guests," proposed by Dr. W. Gordon, and replied to by Professor S. Leduc. The company then repaired to the Rougemont Hotel where a reception was held by the ladies of Exeter.

On August 1st the Continental Anglo-American Medical Society held its annual luncheon at the New London Hotel. Professor W. Osler was in the chair and some 24 members and guests were present. The toast of the guests was proposed by Dr. F. M. Sandwith who intimated that his speech was his swansong, inasmuch as he was resigning his official posts in the society. Dr. G. Newton Pitt and Dr. T. McCrae of Baltimore replied for the guests and so terminated a very pleasant meeting.

On the same afternoon the Irish Medical Schools' and Graduates' Association held its annual summer general meeting and luncheon at the Rougemont Hotel.

The address in Surgery was delivered on Thursday afternoon in the theatre by Mr. Butlin, before a large audience; a full report of this address appeared in our issue of August 3rd, p. 279.

Following this address a garden party given by the Lord Bishop of Exeter at the Palace was attended by some 2000 guests and the weather being fine the beautiful gardens looked their best. Music was provided by the band of the Royal Marines.

pneumococcic infection of the knee-joint coming on acutely with four and five days' *fever* which were opened and drained. 100 *cases* had been collected, 18 *under* one year of age, 17 between one and two *years of age, and 31 from two* to 14 *years.* Infection might occur from the *middle ear*, mouth, tonsil, or pharynx. 50 per cent. affected the knee. The synovial sac was distended and there was absence of redness or brawniness of the skin.

Mr. S. Stephenson (London) said that pneumococcus occurred as pure *culture* in the conjunctiva and, as in gonorrhœal conjunctivitis, joints were *sometimes* secondarily infected.

Mr. Lee and Mr. *Nitch mentioned further cases.*

Mr. Lockhart Mummery read a paper on

Rectal Prolapse,

which for the most part occurred without any of the recognised *causes being recognised*, such as phimosis, stone in the bladder, polypi, or worms. The *occurrence was nearly* equally common in males and *females*. Some had diarrhœa, some *constipation*, and in many more *adenoids* had been removed, but in a large *proportion* there was no ascertainable cause. It *seemed to* be due to general *weakness* and emaciation. There was *practically* nothing but fat round the rectum in *infants*, though later fibrous areolar tissue developed. He was strongly *of* opinion that the *squatting attitude* was *the proper one* for *defæcation* in children, and with the *adoption of this* and *tonic treatment* the *disorder disappeared without* operation. Cauterisation was effective in the worst cases.

Dr. E. Cautley (London), Mr. Lee, and Mr. D'Arcy Power discussed the paper.

Thursday, August 1st.

In opening a discussion on

Acute Nephritis and its Results

Dr. A. F. Voelcker (London) said that from statistics collected *at the Middlesex* Hospital and *at the* Hospital for Sick Children, Great Ormond-street, he deduced the fact that *during the first 36 years of life acute* nephritis showed about *the same incidence in each duodecennial* period and as *regards sex* there was a slight balance in favour of males. In the fever hospitals of the Metropolitan *Asylums Board* 18,000 cases of scarlet fever *included* 842 instances of acute nephritis (about 5 per cent.), of which *only* 29 (or 1 in 30) were fatal. Among *4930 cases of diphtheria* there were 36 instances of acute *nephritis (1 in 137)* without fatality, and the cases of *typhoid fever presented an incidence of 1·6 acute nephritis.* Among *346 cases* of pertussis there were three instances, about the same as in diphtheria. Season exerted no influence. Apart from specific fevers, the etiology so far as could be traced was distributed between the effect of wet and cold, injuries to the skin, especially burns, acute inflammatory states, direct irritants of the kidneys, and a considerable number in which no *suggestion could* be made. *In comparing* children *with adults* it appeared *that* ocular changes and affections of the throat were very rare in the former and in them tendency to recurrence was slight. The principal complications were pneumonia, inflammation of serous membranes, and diarrhœa. Albuminuria might continue for weeks or months, being modified by fatigue, diet, and drug irritation. The issue of cases was in *recovery, chronicity,* or death. Acute nephritis *involving* some, though slight, general symptoms as well as changes in the urine had to be distinguished from renal infarct, paroxysmal hæmaturia, kidney tumours and stone, and angeioneurotic œdema.

Dr. A. W. Sikes (London) did not approve of too exclusive a milk diet and recommended partial substitution of sugar-and-water, as the object of *treatment was to give* physiological *rest to the kidneys.* During convalescence and for chronic cases he recommended a more extended proteid diet, allowing intervals of abstinence. The rise of blood pressure noticed initially in many cases had not been adequately explained. The gastro-intestinal disturbance was referred to the influence of *toxins* on the central nervous *system and* intestinal ulceration might be due to the effect of separated ammonia. *Administration of sodium* chloride was attended by temporary retention of the salt usually associated with œdema of the tissues, and excess of water might increase the œdema, since in the peculiar state of the kidney the urine apparently had a fixed *molecular constitution.* Globulins were present in the *albuminuria of pregnancy* and lardaceous disease. In acute nephritis caffeine and salines should be *avoided* on account *of their direct* irritant effect on the renal epithelium. Hydræmia and œdema were not necessarily associated.

Mr. Stephenson, speaking as an ophthalmic surgeon, *found* ocular *complications* uncommon in acute nephritis in *children. Of those* encountered papillitis was the most *frequent, then amaurosis* (temporary), and more rarely retinal *hæmorrhage and detachment.* Such complications were associated rather with interstitial nephritis. Nettleship in 80 such cases found retinal hæmorrhage in 30. Such *affections* were in the *proportion of* 75 per cent. in interstitial to 14 *per cent.* in parenchymatous nephritis. From the point of view of prognosis retinal changes were *even of* graver augury than *in adults*, death ensuing in from five to 12 *months.*

Dr. Theodore Thomson (London) *referred to* unsuspected nephritis in association with septic *infection* and its almost constant presence in septicæmia and septic endocarditis. In many cases of chronic interstitial *nephritis* there could be *traced septic* infection one or two years previously. *He* referred to a case of double dacryocystitis in which nephritis appeared 14 *days* later. There were lumbar pain and albuminuria, and in the course of two years the *arteries became thickened, blood pressure raised and the heart hypertrophied.* In another case in which chronic nephritis developed after septic infection death from cerebral hæmorrhage occurred three years later. *Toxins were voided* in the urine as witnessed by typhoid fever and their passage *through* the kidneys sometimes excited chronic *nephritis.*

Dr. F. C. Eve (Hull) cited a case in which two ounces *of chlorate of* potash dissolved in water and sipped through the *night for* a *sore throat* produced serious effects. The patient's complexion was of a slaty-blue and yellow tint. The motions were like coffee grounds and the urine was porter-*coloured. Blood* pressure fell till there was suppression of urine. Transfusion with saline solution raised the pressure and some urine was secreted, but death occurred from cerebral hæmorrhage. *He* recommended *dry* cupping the loins and lumbar puncture for the *relief of renal blindness.*

Dr. F. Langmead *(London) referred to* the occurrence of acute nephritis in connexion with tonsillitis and diseases or injuries of the skin. He thought that the milk *régime* was often not continued long *enough.*

Mr. J. Herbert Parsons (London) considered that in children ocular manifestations were conspicuous by their absence. Amaurosis occurred without other *symptoms* and star-figures at the *macula due to* intraocular *pressure* were more common than in adults.

Dr. J. E. H. Sawyer (Birmingham) said that of 55 cases of chronic interstitial nephritis in patients under 21 years of age, which he had *collected*, 22 were in males and 33 in females. In only six cases was there œdema; polyuria extended from birth. In some there had been acute con*genital or intra-uterine nephritis* or *syphilis* with acute interstitial nephritis.

Dr. R. Lees (Glasgow) said that he had known scarlet fever to be followed by chronic interstitial nephritis. Nephritis might also be associated with rheumatism. He favoured the long continuance of milk diet *after* an attack.

Dr. J. P. Parkinson (London), Dr. Cautley, and Dr. Sikes *also spoke.*

Dr. Langmead read a *paper on*

Acetonæmic Conditions in Childhood.

He pointed out that whilst acetone was frequently found in the urine unassociated with symptoms, yet there were many cases in which acidosis occurred *either* by itself *or* as part of the *symptomatology of* other diseases. The symptoms of acidosis were just those of diabetic coma without, however, glycosuria, and were seen unobscured in delayed anæsthetic poisoning and cyclical or recurrent vomiting. He read the notes of three cases of the former condition, two of which had occurred after *chloroform* and one after nitrous-oxide gas, and pointed *out that* it was the state of anæsthesia rather than the anæsthetic which acted as the determining cause. He was able *to* add the notes of two cases of fatal cyclical vomiting and *emphasised* the fact that the post-mortem *appearances, especially* the characteristic buff-coloured *liver, were common* to both conditions. Acidosis was due to the accumulation *of* the products of *fat* disintegration which *had* been imperfectly oxidised by the tissues and organs, *especially the liver.* This might be due to an *inherent want of metabolic* activity, to fats being presented to the *oxidising* organs in two by his new method which largely did away with the personal factor. He gave brief details of the results of his methods as applied to the seven cases, showing that the reaction was given during the attack and disappeared after recovery. One of his cases occurred in association with mumps; it was one of seven cases of that disease in a boys' school. The boy gave a well-marked reaction and recovery occurred.

Dr. G. NEWTON PITT (London) wished to know the mortality in acute cases, especially in those not operated upon. He referred to a case observed by himself and Mr. Dunn occurring after a blow in the epigastrium during a rough voyage from America. Recovery occurred in this case without operation. He also mentioned another case in which operation was performed for abscess and inquired whether in a case which had gone on for three or four months without healing it would be well to explore further from behind with a view to secure better drainage.

Dr. G. CRAVEN MOORE (Manchester) had seen four cases in the post-mortem room, of which three were also seen during life. The condition was usually in persons of obese habit and in alcoholics. Of the four cases he had seen two were hotel proprietors and one was a barman and all of them had indulged in spirits. A history of previous anomalous dyspeptic attacks, regarded as bilious attacks, was common. The actual attack of acute pancreatitis came on suddenly with extreme collapse, and the patient appeared more desperately ill than in acute perforative peritonitis in which there was often for a time a slight reaction. In one case the pain simulated that of acute appendicitis, although the appendix was found to be healthy post mortem. Two of the cases developed acute maniacal delirium with widely dilated pupils. He regarded some of the anomalous attacks of dyspepsia which preceded the final attack as mild attacks of pancreatitis, and in one of his cases there was marked evidence of old inflammatory lesions in the pancreas. He suggested that some of the cases of gastroxynsis or periodic gastrosuccorrhœa might also be of this nature.

Dr. F. J. POYNTON (London) had seen a case of ulcerative endocarditis in a boy in which at the necropsy there was an infarct in the pancreas with inflammation around, and inquired whether this might not be more common than was supposed. He also suggested that the condition in children described by Dr. Gee as the cœliac disease or acholia, in which they passed white stools and wasted rapidly, with evidence of severe abdominal disease, might not be due to some acute disease of the pancreas.

The PRESIDENT of the Association (Dr. HENRY DAVY) described a case of acute pain with tenderness over the appendix occurring in an obese woman, the condition being regarded as appendicitis. After an interval of a fortnight there was a similar attack and then, after three or four months, a large pancreatic cyst developed which was recognised and drained.

Professor W. P. NORTHRUP (New York) pointed out the value of a discussion of this character in drawing general attention to conditions at first regarded as rare, but being found to be more common when carefully looked for.

Dr. W. J. TYSON (Folkestone) referred to the marked simulation of acute pancreatitis by the condition of embolism of the superior mesenteric artery, the chief distinction being the occurrence of some degree of hæmorrhage from the bowel in the cases of embolism.

Mr. C. S. MORRISON (Hereford) referred to certain cases of colitis or epidemic diarrhœa in asylums, the patients passing fatty stools for months and high-coloured urine without jaundice, in one of which he had seen fibrosis of the pancreas.

Dr. H. NOLAN (Cairo) endorsed the resemblance between these cases and those of embolism of the mesenteric artery and referred to a case seen by himself illustrating this.

Professor OSLER, in replying, said in answer to Dr. Newton Pitt that the mortality apart from operation was very high. He did not agree that gastrosuccorrhœa bore any resemblance to pancreatitis. He agreed with Dr. Tyson in regard to the simulation by embolism of the superior mesenteric artery.

A paper (with lantern demonstration) was read by Professor NORTHRUP on

The Treatment of Pneumonia and other Acute Infectious Diseases by Open air Wards in Metropolitan Hospitals.

He described certain shelters erected upon the roof of his hospital in New York in which at first convalescent children and adults were allowed to spend from two to six hours a day. Subsequently special shelters were built like the horse-sheds so common in America. These were protected on the east, north, and west but were open to the south. They were now being used for convalescent patients and cases of various kinds of acute disease were now being entirely treated in these shelters with most satisfactory results. An important feature was that the patients should be made as comfortable as possible, with plenty of warm covering or with hot-water bottles if they required them. Thus far, no single person had caught cold, although there had been snow and cold inclement weather. He was convinced of the value of this adjunct to the wards in metropolitan hospitals.

Dr. P. WATSON WILLIAMS (Bristol) had seen the open-air shelters erected by Professor Northrup and could testify to the comfort and the happiness of the patients.

Sir PHILIP SYDNEY JONES (Sydney, New South Wales), as an advocate for fresh-air treatment of pulmonary tuberculosis, welcomed Professor Northrup's observations and hoped that they would serve to assure those who were afraid of putting their patients out in the open that their fears were unfounded.

Dr. J. MICHELL CLARKE (Bristol) read a paper (with lantern demonstration) on

A Case of Lymphadenoma Treated by X Rays.

The patient was a boy, aged ten years, in whom treatment by x rays caused a marked reduction in the size of the glands so that they were reduced to small swellings like kernels. Death occurred some time later and it was found that the growths in the liver and spleen had been unaffected by the rays. Microscopically the lesions were those of chronic lymphadenoma; there were three kinds of cells, small lymphoid cells, endothelioid cells, and large giant cells, and a peculiar hyaline degeneration of the fibroid tissue which looked like the waxy change but, apart from a slight iodine reaction, gave none of the other tests.

Dr. SAMUEL WEST (London) in a paper called

Some Remarks on the Diagnosis and Treatment of Pericarditis

said the value of the signs of pericarditis varied in the different forms of pericarditis. *Pain* might be absent even when friction was loud. It was usually due to the friction. In large effusion it was rather distension than pain that was complained of. True cardiac pain (angina-like) was rare. *Friction* was localised and if the pericarditis were not in front it would be inaudible. With effusion friction was said to be present at first, to disappear as effusion formed, and to return (redux) as the effusion disappeared. But many cases of large effusion presented loud friction throughout, therefore the presence of friction did not prove the absence of effusion. *The cardiac dulness* was always increased—with effusion of course, but in other forms because of the effect of the inflammation upon the muscle fibres and the dilatation which resulted. The shape of the cardiac dulness with effusion was often described as characteristic and pyriform. This was not so. In moderate effusion it could not be distinguished from that of dilatation of the heart, with which condition confusion had been often made. In large effusion the shape might be pyriform and with the apex not towards the base, but the left axilla. *Systolic recession* of the apex-beat was a valuable sign of adherent pericardium, when it was present, but it was more often absent. The *respiration rate* might be very rapid and the pulse respiration ratio as much perverted as it was in acute pneumonia. The *pulsus paradoxus* only occurred in a typical form with mediastino-pericarditis. All forms of pericarditis might be latent, that was, develop without symptoms. Attention was drawn to the occurrence of latent purulent pericardial effusion after pneumonia. In respect of treatment two questions were considered: (1) the use of opium, which was of great benefit and devoid of risk; and (2) paracentesis. The safest place for puncture was outside the nipple line—the fact that the pleura was perforated here was no objection. All other places were risky. This was also the safest place for excision. The removal of ribs was not necessary and was undesirable. Reasons for these conclusions were given.

The Effect of Oral Sepsis and Antisepsis in Scarlet Fever.

He drew attention to the frequency of septic complications in scarlet fever and differentiated the symptoms of the disease which were strictly scarlatinal and those due to superadded sepsis. He emphasised the effect of oral sepsis—

THE LANCET.

LONDON: SATURDAY, AUGUST 10, 1907.

The Plethora of Congresses.

IN one of his most famous and terrible lines Lucretius, describing the plague at Athens, says of the medical profession,—

> "Mussabat tacito medicina timore."

Happily this can no longer be said of the medical profession in plague or in any other disease, with the possible exception of malignant disease. And nothing shows better the wide-spreading influence of medicine than the subjects debated at the five congresses which have been sitting during the past week. The British Medical Association ended its labours at Exeter on August 3rd, the British Association for the Advancement of Science concludes its meeting at Leicester this week, as do the International Congresses on Housing and on School Hygiene which sat during this week at the Caxton Hall and at the University of London respectively. In addition to the above-mentioned the International Congress of the Medical Press has also been holding meetings in London during the last and the present week. If we reported every word of the proceedings at all these five congresses we might very fairly expect that the reports would interest our readers, for they all deal with matter which is at least germane to medical science. Space and time fail us to report the whole proceedings. It is a physiological fact that if one of the higher organisms be supplied with too much food at a time the following things will happen. Either the food is vomited as a crude undigested mass or an acute paralysis of the digestive tract sets in, or the animal refuses its food. We are unwilling for our readers' sake to adopt course number one, for our own sakes we cannot be expected to adopt number two, and therefore we are reluctantly compelled to follow course number three and to refuse a great deal of the pabulum set before us. But, thanks to our fellow workers in the lay press, both daily and weekly, much responsibility is taken off our shoulders, for the lay press, which is becoming daily more and more informed upon medical and other scientific matters, is both able and willing to devote space to the discussion of the various matters which are being debated at the several congresses and many of which have a very distinct public interest.

The majority of the detailed accounts which appear in our own columns have to be mainly confined to the proceedings of the British Medical Association, but this would certainly not be the case were it not that the dates of the various congresses all clash. Housing and school hygiene are both subjects which are very distinctly medical matters, for they deal with the health of the body politic in a very far-reaching fashion. Housing—i.e., healthy housing—is of vast importance to all those who are alive at the present date and, in a way, to future generations, for a generation which is badly housed cannot be expected to produce healthy offspring, who will be the fathers and mothers of future generations. And so, too, the subject of school hygiene affects the children of the present and through them those of the future. But although we are unable to devote so much space as we should like to the congresses in question, yet in a way we are always reporting them, for hardly a week passes without some, or all, of the subjects now receiving public ventilation being discussed in our columns. With regard to one congress—namely, the International Congress of the Medical Press—it may be thought to concern ourselves rather than our readers. It must be remembered, however, that a strong medical press has its value for the community. Questions of hygiene, of pure food, of quackery, and of other matters which concern the public health can only be actively dealt with in a strong and united medical press. The world is now grown so small, the community of interests among the various nations is so marked, and intercommunication between them is so free, that almost any question affecting the public health of one nation is affected by and affects the public health of other nations. The medical press can be an influence with Governments upon these matters, and although at present medicine has not as much influence in shaping legislation as we should like to see, the force of scientific opinion is growing in strength. Only last week—i.e., on August 2nd—the President of the Local Government Board, in moving the second reading of the Public Health (Regulations as to Foods) Bill, paid a generous tribute to the medical press in general and ourselves in particular for the urgent requests for legislation with regard to putrid foodstuffs. Recognition in one country of the value of medical views must encourage sanitary reformers in other countries, and, therefore, any methods which will bring about community of action between the medical journals of the different countries can only result in the good of the peoples.

An Antivivisection Debate.

No one who acknowledges that in physiological and pathological research it is legitimate to employ the lower animals is in the least afraid of publicity. The opposition to vivisection which in some quarters exists is founded for the most part on a lack of knowledge of the facts of the case. Misrepresentation, sometimes accidental and sometimes intentional, is responsible for much of the fervour with which antivivisectionists wage war against the present Act by which experiments on animals are licensed. Even if no Act were in force, it is intensely improbable that any real abuse would exist, but with the safeguards provided by the Act no harm can possibly be done. The present claim of the antivivisectionist societies is that every form of experiment on animals should be made illegal, so that not even a hypodermic injection of an animal should be allowed. This attitude is, as we have said, largely due to a want of knowledge, and nothing but good can come of a thorough ventilation of the subject. We, therefore, can speak with approval of the holding of a public debate at Glossop between two medical men [illegible] by his new method which largely did away with the personal factor. He gave brief details of the results of his methods as applied to the seven cases, showing that the reaction was given during the attack and disappeared after recovery. One of his cases occurred in association with mumps; it was one of seven cases of that disease in a boys' school. The boy gave a well-marked reaction and recovery occurred.

Dr. G. Newton Pitt (London) wished to know the mortality in acute cases, especially in those not operated upon. He referred to a case observed by himself and Mr. Dunn occurring after a blow in the epigastrium during a rough voyage from America. Recovery occurred in this case without operation. He also mentioned another case in which operation was performed for abscess and inquired whether in a case which had gone on for three or four months without healing it would be well to explore further from behind with a view to secure better drainage.

Dr. G. Craven Moore (Manchester) had seen four cases in the post-mortem room, of which three were also seen during life. The condition was usually in persons of obese habit and in alcoholics. Of the four cases he had seen two were hotel proprietors and one was a barman and all of them had indulged in spirits. A history of previous anomalous dyspeptic attacks, regarded as bilious attacks, was common. The actual attack of acute pancreatitis came on suddenly with extreme collapse, and the patient appeared more desperately ill than in acute perforative peritonitis in which there was often for a time a slight reaction. In one case the pain simulated that of acute appendicitis, although the appendix was found to be healthy post mortem. Two of the cases developed acute maniacal delirium with widely dilated pupils. He regarded some of the anomalous attacks of dyspepsia which preceded the final attack as mild attacks of pancreatitis, and in one of his cases there was marked evidence of old inflammatory lesions in the pancreas. He suggested that some of the cases of gastroxynsis or periodic gastrosuccorrhœa might also be of this nature.

Dr. F. J. Poynton (London) had seen a case of ulcerative endocarditis in a boy in which at the necropsy there was an infarct in the pancreas with inflammation around, and inquired whether this might not be more common than was supposed. He also suggested that the condition in children described by Dr. Gee as the cœliac disease or affection, in which they passed white stools and wasted rapidly, with evidence of severe abdominal disease, might not be due to some acute disease of the pancreas.

The President of the Association (Dr. Henry Davy) described a case of acute pain with tenderness over the appendix occurring in an obese woman, the condition being regarded as appendicitis. After an interval of a fortnight there was a similar attack and then, after three or four months, a large pancreatic cyst developed which was recognised and drained.

Professor W. P. Northrup (New York) pointed out the value of a discussion of this character in drawing general attention to conditions at first regarded as rare, but being found to be more common when carefully looked for.

Dr. W. J. Tyson (Folkestone) referred to the marked simulation of acute pancreatitis by the condition of embolism of the superior mesenteric artery, the chief distinction being the occurrence of some degree of hæmorrhage from the bowel in the cases of embolism.

Mr. C. S. Morrison (Hereford) referred to certain cases of colitis or epidemic diarrhœa in asylums, the patients passing fatty stools for months and high-coloured urine without jaundice, in one of which he had seen fibrosis of the pancreas.

Dr. H. Nolan (Cairo) endorsed the resemblance between these cases and those of embolism of the mesenteric artery and referred to a case seen by himself illustrating this.

Professor Osler, in replying, said in answer to Dr. Newton Pitt that the mortality apart from operation was very high. He did not agree that gastrosuccorrhœa bore any resemblance to pancreatitis. He agreed with Dr. Tyson in regard to the simulation by embolism of the superior mesenteric artery.

A paper (with lantern demonstration) was read by Professor Northrup on

The Treatment of Pneumonia and other Acute Infectious Diseases by Open-air Wards in Metropolitan Hospitals.

He described certain shelters erected upon the roof of his hospital in New York in which at first convalescent children and adults were allowed to spend from two to six hours a day. Subsequently special shelters were built like the horse-sheds so common in America. These were protected on the east, north, and west but were open to the south. They were now being used for convalescent patients and cases of various kinds of acute disease were now being entirely treated in these shelters with most satisfactory results. An important feature was that the patients should be made as comfortable as possible, with plenty of warm covering or with hot-water bottles if they required them. Thus far, no single person had caught cold, although there had been snow and cold inclement weather. He was convinced of the value of this adjunct to the wards in metropolitan hospitals.

Dr. P. Watson Williams (Bristol) had seen the open-air shelters erected by Professor Northrup and could testify to the comfort and the happiness of the patients.

Sir Philip Sydney Jones (Sydney, New South Wales), as an advocate for fresh-air treatment of pulmonary tuberculosis, welcomed Professor Northrup's observations and hoped that they would serve to assure those who were afraid of putting their patients out in the open that their fears were unfounded.

Dr. J. Michell Clarke (Bristol) read a paper (with lantern demonstration) on

A Case of Lymphadenoma Treated by X Rays.

The patient was a boy, aged ten years, in whom treatment by x rays caused a marked reduction in the size of the glands so that they were reduced to small swellings like beans. Death occurred some time later and it was found that the growths in the liver and spleen had been unaffected by the rays. Microscopically the lesions were those of chronic lymphadenoma: there were three kinds of cells, small lymphoid cells, endothelial cells, and large giant cells, and a peculiar hyaline degeneration of the fibroid tissue which looked like the waxy change but, apart from a slight iodine reaction, gave none of the other tests.

Dr. Samuel West (London) in a paper called

Some Remarks on the Diagnosis and Treatment of Pericarditis

said the value of the signs of pericarditis varied in the different forms of pericarditis. Pain might be absent even when friction was loud. It was usually due to the friction. In large effusion it was rather distension than pain that was complained of. True cardiac pain (angina-like) was rare. *Friction* was localised and if the pericarditis were not in front it would be inaudible. With effusion friction was said to be present at first, to disappear as effusion formed, and to return (redux) as the effusion disappeared. But many cases of large effusion presented loud friction throughout; therefore the presence of friction did not prove the absence of effusion. *The cardiac dulness* was always increased—with effusion of course, but in other forms because of the effect of the inflammation upon the muscle fibres and the dilatation which resulted. The shape of the cardiac dulness with effusion was often described as characteristic and pyriform. This was not so. In moderate effusion it could not be distinguished from that of dilatation of the heart, with which condition confusion had been often made. In large effusion the shape might be pyriform and with the apex not towards the base, but the left axilla. *Systolic retraction* of the apex-beat was a valuable sign of adherent pericardium, when it was present, but it was more often absent. *The respiration rate* might be very rapid and the pulse respiration ratio as much perverted as it was in acute pneumonia. *The pulsus paradoxus* only occurred in a typical form with mediastino-pericarditis. All forms of pericarditis might be latent, that was, develop without symptoms. Attention was drawn to the occurrence of latent purulent pericardial effusion after pneumonia. In respect of treatment two questions were considered: (1) the use of opium, which was of great benefit and devoid of risk; and (2) paracentesis. The safest place for puncture was outside the nipple line—the fact that the pleura was perforated here was no objection. All other places were risky. This was also the safest place for incision. The removal of ribs was not necessary and was undesirable. Reasons for these conclusions were given.

obtain a living wage for their labour. The first question which the committee endeavoured to find an answer to was, What proportion of women who practised as so-called midwives have retired since the coming into force of the new Act and what proportion of those on the roll are actually practising midwives? From the figures obtained it would appear that a very large number of these women have retired from practice since the year 1902. Thus we find that out of a total of 5939 midwives who were practising in six counties no less than 2629 had signified their intention to retire up to October, 1904. At the end of 1906 the total number of midwives on the roll was 23,278, and of these it was estimated that only 14,450 were practising, the remainder being engaged in monthly nursing. The number of untrained midwives on the roll is of necessity at the present time very large owing to the fact that no less than 12,521 women were placed on the roll in virtue of their having been in practice as midwives for the 12 months preceding the passing of the Act. A table given in this report demonstrates that the proportion of untrained midwives practising at the present time is enormous. Thus, of a total of 4898 midwives practising in 18 counties or boroughs the number of those trained is estimated at only 856. The important questions as to the average rate of payments of midwives and the average number of cases attended during a year the committee had great difficulty in answering. The conclusion which it came to, largely from information supplied by one of its number, Miss ALICE GREGORY, is that in unpauperised rural districts the average fee is 10*s*., not, however, as a rule paid entirely in money. The number of cases attended by each midwife is still more difficult to ascertain with certainty. From the statistics collected by the committee it would appear that an average of 18 cases per annum is about the number attended in small urban and rural districts, while in the larger boroughs the average may be as much as 61 cases. As Mr. A. G. R. FOULERTON points out, it would appear that the total number of midwives judged merely by the actual number of births is very much in excess of that required. If we assume with the committee that only 62 per cent. of the women on the roll, or some 14,430, are practising, and that about 50 per cent. of the total number of births, which for 1906 was 934,391, in England and Wales are attended by midwives, then the average yearly number of cases attended by each midwife would be about 33, representing a total earning of about £16 10*s*. It must, however, be remembered that the demand for the services of these women varies very considerably in different localities and we can therefore come to no other conclusion but that comparatively few of the midwives in practice at the present time are earning a living wage, and that in sparsely populated country districts it is simply impossible for them to do so unless working in association with some county or charitable association.

The information presented in this report cannot but be very disquieting to those who have the interests of a valuable class of the community at heart. The problem is one of much difficulty and the outlook for those women who think of becoming midwives, and who can often but ill-afford the expenses attending the necessary training to enable them to obtain the certificate of the Central Midwives Board, is by no means an encouraging one. They may, and indeed will, have the greatest difficulty in obtaining adequate remuneration, or indeed even a bare living wage, when their training is completed. It will be seen, therefore, that the Association for Promoting the Training and Supply of Midwives has before it a hard task and one which will call for considerable talents of ingenuity and persuasiveness if it is to place the midwifery service of the poor, as contemplated by the Midwives Act, upon a sound financial basis. The association has worked, and is working, very hard, but the course ahead of it is a stiff one.

◆

Alcohol, Tobacco, and Accuracy.

IN our issue of last week we commented upon the three addresses delivered at the recent meeting of the British Medical Association by Dr. H. DAVY, Dr. W. HALE WHITE, and Mr. H. T. BUTLIN. The key-note of all three addresses was accuracy: the careful record of facts, founded upon systematic experiment and the knowledge derived thence, which is the only true knowledge. If the writers of these three addresses had wished to exhibit "a fearful example" of the evil which they desired to combat they would have found one ready to their hand in the consideration of the proceedings which took place on Thursday, August 1st, and Friday, August 2nd, at the breakfast given by the Science and Education Committee of the National Temperance League and at the proceedings in the section of State Medicine respectively. At the former meeting Dr. DAVY appeared in the rôle of a Balaam and, while in no way minimising the evils of alcoholism, denounced "most of the temperance societies and a large number of the temperance advocates" for talking "the most unscientific twaddle ever invented." Dr. DAVY'S words receive a notable confirmation in a book, entitled "The Licensed Trade," which was reviewed in our columns last week and the author of which, Mr. E. A. PRATT, was brought up a teetotaler. In his later years, however, he made an independent examination of the question and came to the conclusion that many of the statements made by total abstainers were based largely on "exaggeration, misconceptions, and, indeed, conditions altogether incapable of attainment." The result of his emancipation from the ideas in which he was educated has been to transform him into a frank advocate of the virtues of light beer, and it is impossible to doubt that the same change of view would take place in many champions of teetotalism if they understood their subject and were not bent fanatically upon confounding the moderate drinker with the drunkard. The users of alcohol are not the only persons who may want lessons in moderation, and Dr. DAVY rightly drew attention to the abuse of tea, especially when given to children; amid expressions of dissent he maintained that a meal of cheese, bread, and light beer was an infinitely more scientific meal than the "food which children were now getting of bread, tea, and jam." He insisted at the same time on the value of temperance and the teaching thereof, only the teaching must be founded on scientific fact and not tinged with personal opinion. The scientific facts, said he, that we do know are that alcohol is not a necessity of life and is rarely was inclined to think that surgeons were not always gentle enough in their manipulation of the abdominal organs, and he was sometimes surprised at the small amount of shock. In some operations, such as for the removal of an enlarged thyroid, it was becoming customary to employ local anæsthesia, but really he had had no trouble in giving general anæsthetics to thyroid cases.

Mr. C. A. LEEDHAM-GREEN (Birmingham) wished to urge strongly the claims of spinal anæsthesia. He began to employ it some 18 months ago. It was especially useful when any bronchitis was present, but now he used spinal anæsthesia for all major operations below the diaphragm. He had tried stovaine and novocaine but now he used tropacocaine and it was by far the best; it was less likely to give rise to headache or vomiting, it was less toxic than the others, and it had less action on the motor cells. He considered that the addition of adrenalin was wholly unnecessary and undesirable. The patient was first given a diffusible stimulant; whisky was usually employed. An exploring needle was inserted between the second and third lumbar vertebræ or, if high anæsthesia was required, between the first and second. As soon as the cerebro-spinal fluid flowed clearly and freely the tropacocaine was injected. One cubic centimetre of a 5 per cent. solution was put into the syringe and then some of the cerebro-spinal fluid was drawn into the syringe and the mixture was injected. There was no need to put the patient into the Trendelenburg position, for the onset of anæsthesia was very rapid—so rapid, indeed, that he never needed to test for it, but he commenced the incision as soon as the patient lay down and he (the surgeon) had washed his hands. The anæsthesia was generally up to the fourth rib; occasionally it was up to the clavicle and very rarely it might not reach above the costal arch. As a rule the anæsthesia lasted for one and a half hours and usually it was absolutely ideal. It was not suitable for severe kidney or gall-stone operations, though if morphine and scopolamine be injected previously it might be sufficient. When the peritoneum was acutely inflamed he did not recommend spinal anæsthesia, as the serous membrane was extremely sensitive. After the operation, vomiting might take place, but it was rare and only one vomit occurred, or there might be a little headache for a few hours. He did not regard nervousness as a contra-indication, for the patient soon lost her anxiety and might even sleep by suggestion. On the evening of the day of operation an ounce of castor-oil was given. Spinal anæsthesia was especially suitable if there was bronchitis, nephritis, diabetes or alcoholism. It was very convenient for catheterising the ureter in the male. It was contra-indicated in children (his youngest case was 12 years old), in the highly neurotic, in severe septic conditions especially of the skin, in acute peritonitis, and in long, difficult operations above the umbilicus. Most of the fatal cases had been with cocaine and stovaine. In 2000 cases in which tropacocaine was used, no death occurred. One disadvantage was that the patient heard what was said.

Dr. A. G. LEVY (London) said that there was apparently an attack on general anæsthetics and there were objections to some general anæsthetics. If ether was given by the open method it was an absolutely perfect anæsthetic. When given in the *ordinary* way, as in a Clover's inhaler, there was partial asphyxia and this caused venous congestion and violent movements of the abdominal muscles. If ether were given by the open method there was no cyanosis and the after-condition of the patient was excellent. It was true that the induction period was prolonged by some three minutes and more ether was used, but these were small matters when the safety and comfort of the patient were concerned. With regard to shock, spinal anæsthesia might stop ordinary sensory impulses, but it did not block emotional impulses.

Mr. J. W. STRUTHERS (Edinburgh) had been interested for some years in local anæsthesia. Its main field was in minor operative work, where the area was small and could be completely covered. Sometimes perineural or intraneural injections were required. Varicocele and the radical cure of hydrocele were typical operations for local anæsthesia. Attempts to employ local anæsthesia for wider operations were ill-advised. It was not suitable for abdominal operations as the area of operation could never be exactly known beforehand.

Professor W. L. RODMAN (Philadelphia) thought the result of the present advance of injection anæsthesia must depend on the decision as to the relative importance of the real dangers of general anæsthetics and the less known risks of injection anæsthesia. He considered that spinal anæsthesia was suitable for cases with bronchitis and nephritis, in cardiac cases, and in alcoholics. He had employed it in about 100 cases and had never regretted using it. He thought that there should be some special indication. In one case he had found it very useful; it was a case in which a man had sat down on a pitchfork and had torn both sphincters of the anus; spinal anæsthesia had allowed him to have the assistance of the voluntary movements of the patient, and a result was obtained which he thought would have been impossible with a general anæsthetic. He did not think spinal anæsthesia was suitable for children.

Dr. J. SINGLETON DARLING (Lurgan) described a case in which he had employed infiltration anæsthesia. The patient was a woman, aged 75 years, from whom he removed an ovarian cyst. There were many adhesions and the operation lasted one hour and 20 minutes, but she complained of no pain except when traction was made on the intestine.

Mr. E. CANNY RYALL (London) said that he had been much interested in the subject of spinal anæsthesia for some time. He used novocaine; he thought it was much better than stovaine and better even than tropacocaine. He had a case of an old man in which he removed an enlarged prostate; the heart was weak but no shock appeared, and within a few minutes of the termination of the operation he was able to talk to his wife and daughter. Mr. Canny Ryall mentioned that death had occurred when tropacocaine had been used. He gave castor-oil before the operation, with three grains of pyramidon, and the head was always kept up. In this way he avoided the headache which was liable to follow spinal anæsthesia. He used a 1 per cent. solution of novocaine with a synthetic adrenalin. If the operation was above the umbilicus he used in addition morphine and scopolamine.

Dr. G. A. H. BARTON (London) thought that spinal anæsthesia was dangerous. In 3 per cent. of some published cases the anæsthesia was a failure and in 3 per cent. there was severe headache. He described a case in which marked œdema had followed the employment of spinal analgesia.

Mr. J. G. PARDOE (London) read a paper on

The Indications for Prostatectomy.

He urged the importance of discriminating between the various forms of enlarged prostate. When malignant disease affected the prostate enucleation was impossible and even excision was only possible at an early stage. The examination of an enlarged prostate must be systematic; the shape, outline, consistence, size, fixity, and the presence of enlarged lymphatic glands must all be considered. In all cases the suprapubic route was best, except for fibrous enlargement, for which prostatotomy was the most suitable operation The surgeon should not refuse to operate for adenomatous enlargement, even if the patient was very ill.

Mr. P. J. FREYER (London) read a paper on

A Further Series of 107 Cases of Enucleation of Enlarged Prostate.

He showed many of the specimens removed, which ranged in weight from half an ounce to over 11 ounces. Nine of the patients were over 80 years of age. When uræmic symptoms were present, a dry tongue and thirst, the operation was best done in two stages, the bladder being opened at the first operation and the enucleation completed later. There were seven deaths in the 107 cases. In all he had performed the operation 432 times, with a mortality of 7 per cent. Cancer of the prostate was not so rare as was formerly thought and it must not be forgotten that malignant prostates did not necessarily bleed.

Dr. WARD COUSINS read a paper on

A Case of Composite Odontome.

A boy, aged 10 years, had a swelling of the right side of the jaw; this steadily increased and when Dr. Ward Cousins removed it it was found to be a composite odontome and over 100 denticles were present.

Mr. C. P. CHILDE (Southsea) read a paper on

A Case of Successful Resection of Nine and a Half Feet of Small Intestine for Gangrene.

The patient was a woman, aged 59 years, and she had had a femoral hernia for 17 years and it had been strangulated on one occasion. She was attacked with severe abdominal pain a quarter of an hour after rising in the morning. The hernia was large and it was thought to be strangulated. When the sac was opened the bowel was found to be make a document a forcible one; the further importance of the document under consideration lies in the remarkably clear exposition of the facts, in the lucid and straightforward reasoning, and in the frank enunciation of conclusions. The story of the Mulkoval disaster has been obscured by much adventitious matter, and some previous pronouncements on the case have been distinctly unfortunate. The origin of the accident has been examined by two bodies, the Jenkins Commission in India and the Lister Institute, and the conclusions reported by these bodies have been accepted as the official view. But these two bodies did not agree with each other. The Jenkins Commission ascribed the contamination of the bottle with which the accident was connected to the Bombay laboratory. The Lister Institute was asked to report on this finding and submitted three versions of its own opinion; but neither of these versions coincided with the Jenkins Commission's conclusions, nor did they coincide with each other. Against the four divergent pronouncements made by the Jenkins Commission and the Lister Institute we have now a strikingly conclusive and unanimous statement made by men qualified to judge of all the scientific questions involved and absolutely removed from possibility of bias. Their verdict, given in terms free from any ambiguity, is that the facts of the case indicate clearly that the contamination of the Haffkine prophylactic did not date from the time of its preparation in the Bombay laboratory and that therefore discussion on the methods of cultivating and preparing the prophylactic is not relevant to the question; that, on the other hand, there is very strong evidence to show that the contamination took place when the bottle was opened at Mulkoval in a manner which violated the technique prescribed by the Bombay laboratory. As we have already pointed out, the finding against the Bombay laboratory has not been supported by facts, but the Government has published that finding and invites the public to accept it with confidence. We invite the public to do exactly the reverse, for close consideration of all the circumstances of the case makes it impossible to subscribe to the official view. Mr. Morley has said in the House of Commons that this is "a matter respecting which no conclusion can be arrived at with absolute certainty." Such an attitude, we hope that he will see, ought not to be persevered in. The inaction of the Government cannot any longer be defended by any assertion that the two independent bodies which have reported upon the matter came to a unanimous verdict. Their verdicts differ, and against them a mass of testimony, which we think unimpeachable, is offered. Mr. Morley is the exact man to face such a situation nobly; we trust that he may be brought to see that justice to Mr. Haffkine requires an earnest reconsideration of the official attitude upon the matter.

TRIPLETS.

THERE is always a considerable amount of interest attending the birth of triplets, not only from the rarity of the occurrence, about once in 7000 births, but also because, as Ballantyne points out, pregnancies with more than two children must be considered as teratological. In THE LANCET of July 20th, p. 157, Dr. Robert Ollerenshaw records a very interesting case in which a girl aged 16 years was delivered of triplets, the labour being complicated by an attack of eclampsia. The fœtuses were delivered artificially and were born alive. The account of the case, as published in our columns, does not include their after-history but, as might have been expected, they all died in a very brief space of time. The mother made a good recovery from her attack of eclampsia. There are several points of much interest in this case. The fact that more boys than girls are born in the whole population appears to hold good also in the case of triplets and in this instance the three children were all males. Unlike the present case, the three fœtuses are most commonly of different sexes, but while it is true that uniovular fœtuses are always of the same sex yet this may be so even when the fœtuses are derived from two or three ova. There were two placentæ joined at their edges and two chorions, so that the case is one of biovular triplets, the commonest arrangement in this condition; uniovular triplets are exceedingly rare, only nine well-established cases having been recorded in all. It is a most curious circumstance that the influence of heredity, illustrated in the present case in the history that two aunts of the patient had given birth to twins, does not seem to hold good in the case of uniovular triplets but does in the case of those developed from two or three ova. The history of the father's family would have been of much interest since there are good grounds for believing that the hereditary influence is decidedly greater when not only the mother but also the father are members of a prolific family. The tendency to the production of multiple pregnancies certainly seems to increase from generation to generation. In this connexion a most interesting case has been published by Professor F. von Winckel in which the hereditary influence was transmitted through the males for four generations, six twin pregnancies being met with in nine labours, occurring twice in the second, three times in the third, and once in the fourth generation. The extreme youthfulness of the two parents is noteworthy. The average age of the mother of triplets, as Dr. Ollerenshaw points out, has been shown to be about 32 years and in only 1·79 per cent. of Mirabeau's cases was the mother between the age of 15 and 19 years. The birth of triplets in a first pregnancy is also quite the exception, in 80 per cent. of the cases the mother being a multipara. As is well known, the occurrence of such a complication as eclampsia is predisposed to by the presence in the uterus of more than one fœtus and in this respect, too, the case described by Dr. Ollerenshaw is of interest.

THE CLASSIFICATION OF DISEASE AND CAUSES OF DEATH.

ANY system of registration of the causes of death or the incidence of disease presupposes the existence of a nosological classification. Of such classifications many have at various times been proposed, varying in their nature according to the state of contemporary medical knowledge and the objects which their authors had in view when compiling them. A very full account of this intricate subject has been given by Mr. G. H. Knibbs in a long paper entitled "The Classification of Disease and Causes of Death from the Standpoint of the Statistician," which was recently read before the Victorian branch of the British Medical Association. Mr. Knibbs, who is the Australian Commonwealth statistician, said that the scheme of any classification is determined by its specific aim as well as by the state of knowledge at the time of its preparation. For instance, attention may be directed principally to the causes of diseases, or to their pathological manifestations as seen by the naked eye or under the microscope, or to their clinical symptoms. He believed that the first attempt to classify diseases comprehensively on a natural history plan was made by François Bossier de Lacroix, otherwise known as Sauvages (1706–1767), and the result was embodied in his "Nosologia Methodica." This work was followed by the "Synopsis Nosologiae Methodicae" of Dr. William Cullen of Edinburgh, published in that city in 1785. The "Nomenclature of Diseases" of the Royal College of Physicians of London first appeared in 1869, and the fourth edition (third revision) was brought out in 1906. Nearly all the English nomenclatures in actual use are said to be more or less directly derived from that of Dr. William Farr—that is to taken by medical practitioners, and in the case of Philadelphia a very complete system of milk inspection had been organised which included both chemical and bacteriological examination and a systematic and periodic veterinary inspection of milch cows. Certificates were issued by the commission and dairies holding this certificate commanded a much higher price.

Dr. F. E. WYNNE (Leigh, Lancs.), speaking as a member of the town council of Leigh, supported the idea of placing the duty of inspection upon county councils. He thought local authorities were already overburdened with inspectorial duties.

Dr. F. J. H. COUTTS (Blackpool) regretted that no one was present on behalf of dairy farmers and to put forward the view which they expressed that milk-borne disease was solely due to home and distributive contamination. He also felt that proper isolation of tuberculous beasts must be accompanied by sufficient reasonable compensation. He advocated refrigeration and cooling as equal to pasteurisation, to which certain chemical objections could be urged. In Ireland in some places milk was unprocurable by the poor owing to the prices paid by the creameries.

Dr. A. DRURY (Halifax) spoke of his experience of home contamination as a factor in infantile mortality.

Mr. SACK NOY SCOTT (Plymstock) spoke briefly on his experience of rural cowsheds and said that in his own district much good work had been done under the regulations.

Dr. W. B. BARCLAY (Weymouth) criticised the conclusions arrived at by Dr. Routley, having himself at one time been medical officer of health of Aldershot. His experience had been that the condition of the cowsheds at the source was of the very worst and would produce infantile diarrhœa.

Mr. E. H. T. NASH (Beccles) spoke more especially from the point of view of the London infantile mortality statistics. He had had experience of the milk from the Walker-Gordon laboratories and found that it was the most perfect milk he had ever used. He condemned sterilised milk but would be willing in certain months to use pasteurised milk and occasionally condensed milk but not as a rule. The existence of scurvy could not be overlooked.

Dr. W. F. BROWN (Ayr) spoke of the great difficulties caused by deficient water-supplies and said that pressure was needed by the authorities on the landlord even more than on the tenant. Tuberculosis was not wholly due to milk but a great deal was due to bad feeding other than bad milk. Milk must be the subject of preventive treatment and not cleaned after it had been made dirty.

Mr. O. H. WATTS PARKINSON (Wimborne) spoke of the importance of controlling imported dairy products and the need for enforcing existing regulations There should be a greater power of punishment for supplying milk containing pus, dirt, &c., and some form of notification of disease among cows. Security of tenure was more essential in dealing with rural conditions than in any other districts because the farmers and dairymen controlled the councils.

Dr. W. A. BOND (London) spoke further of the Walker-Gordon laboratories and the good work which was being done there. The present failure to control infantile tuberculosis reflected gravely on our modern civilisation, because while the adult death-rate from pulmonary tuberculosis had been reduced one-third infantile tuberculosis had remained stationary.

Dr. J. H. DRYSDALE (London) added a few remarks on the private hygiene as part of the question.

Mr. GIBSON spoke from the general practitioner's point of view and felt that it was to this branch of the profession that much that was said applied. It was in the power of the private practitioner largely to influence the condition of the milk supply both at the source and more especially at the home.

Professor KENWOOD briefly replied, and Mr. HERBERT JONES then moved the following proposition :—

> That it is necessary for the efficient and operative inspection of rural milk-supplies that such inspection should be made by officers not subject to periodical reappointment.

This was carried unanimously.

OBSTETRICS.

WEDNESDAY, JULY 31ST.

After a few introductory remarks by the PRESIDENT, Dr. E. H. TWEEDY (Dublin), on the Morbidity of Childbirth a discussion on

The Justification for Artificial Dilatation of the Cervix to Hasten Delivery at Full Term, with a Discussion on the most Appropriate Method for Procuring this Dilatation,

was introduced by Dr. ROBERT JARDINE (Glasgow). He said that the first part of the subject—viz , the justification of the operation—need not occupy much time. The operation had been so long in use that use and wont alone might seem sufficient justification. He held no justification to be necessary for an operation which enabled one to save life. Undoubtedly, conditions sometimes arose where in the interests of the child or of the mother, or of both, a quick delivery was necessary, and if that delivery were to be carried out through the natural passages artificial dilatation of the cervix was required. The operation, perfectly justifiable under certain conditions, deserved reprobation if done when there were no strong reasons for it. The speaker entered a protest against such a proceeding. Dr. Jardine first described the methods which approached nature's ways, by means of hydrostatic bags or the vaginal plug. These methods were slow and uterine action was called into play by them. Of the bags he considered the firm ones—like Champetier de Ribes's—more useful than the rubber ones of Barnes. He had found the vaginal plug most useful in placenta prævia, but much depended on the proper insertion of the plug. Manual and bimanual methods were next described. Manual dilatation was the one most frequently employed and most useful when the cervix was soft and partly dilated. Dilatation by expanding instruments, like Bozzi's, acted much like the hand, but the arms were not sensitive and therefore gave no indication when the parts were tearing. These screw-instruments required to be used with great care and at least half an hour ought to be occupied in the operation. If the cervix was not "taken up" very great caution was necessary. Cutting methods.—Multiple incisions of the cervix, as recommended by Dührssen. The cervix should be obliterated. The number of incisions varied from two to seven. There was risk of the lateral incisions extending, so as to cause injuries to the uterine arteries, and in making the incisions the lateral position should be avoided, more especially when making four incisions. The child should be delivered at once, preferably by forceps, and after the placenta was away the cervix should be drawn down for careful inspection. If there was bleeding the incision should be stitched, but if there was no bleeding stitching was not absolutely necessary. Vaginal Cæsarean section.—Dührssen's name was also associated with this operation, but he had not been the first to perform it, although he was the first to suggest it. Effacement of the cervix was not necessary and it was preferable that the presenting part should not have engaged as version was the method of delivery usually adopted. One very essential condition was that the uterus should be mobile, so that the cervix and lower uterine segment could be pulled well down. Dr. Jardine described the operation and also Dührssen's perineo-vaginal incision to enlarge the vagina. He did not think this incision necessary, as the vagina could be dilated manually. It had been maintained that the operation was a very easy one and quite free from risk. Occasionally even an expert would find it a difficult one to perform and the not inconsiderable death-rate of published cases amply proved it to be not by any means free from risk. The risks were : 1. *Infection*, which was common to all operations but less in vaginal than in abdominal ones. To guard against this the strictest asepsis was necessary. 2. *Injuries to the mother or child*. The uterus might be ruptured by extension of the incision and the bladder had been injured. In regard to the child it had been born dead and craniotomy had been found necessary. 3. *Hæmorrhage*. This was fairly common, as the uterus was atonic. In all cases it was necessary to be prepared to tampon. Dr. Jardine considered that vaginal Cæsarean section was an operation for experts in vaginal surgery and not one which an ordinary general practitioner should undertake. In conclusion Dr. Jardine said that in deciding on the proper method to adopt the attendant had to consider the condition of the cervix and also the amount of his experience. If he were an adept in vaginal surgery he would probably prefer vaginal Cæsarean section in all cases in which there was likely to be difficulty in dilating the cervix, but if he had no experience in that form of surgery, in the interest of his patient he should adopt one of the other methods or else call in the assistance of an experienced colleague, who could undertake the major operation of vaginal Cæsarean section. In reference to the final letter from the hospital Sir William Treloar, although expressing his sincere congratulations on what has been accomplished by it in the cause of the cripples, did not see his way to a fuller acknowledgement of its claims to priority in the enterprise which he has so deeply at heart. The excellence of his own cause can surely in no way suffer diminution because Liverpool and not London has first demonstrated its value practically.

THE LONDON MILK-SUPPLY.

THE tuberculous milk clauses which are included in the General Powers Bill of the present year of the London County Council have now been accepted by Committees of both Houses of Parliament and there is every prospect that they will become law during the present session. The clauses are practically the same as those which are known as the "model clauses." In some small details they have been altered to meet the views of the County Councils' Association and are in their application to the circumstances of London somewhat modified to meet the exceptional position which the City of London enjoys. The County Council is to administer these new powers but in respect of the City the City Corporation is to have concurrent powers and be authorised as to the way in which they should be exercised. The City Corporation is sure not to be backward in its desire to see diminished the risk of tuberculosis among its population. The London County Council will be empowered to take samples of milk, to examine them for the tubercle bacillus, to visit farms from which tuberculous milk is received, to examine the cows therein, and to prohibit the supply within London of milk derived from cows found to be suffering from tuberculous disease of the udder. While the London population will welcome this additional safeguard to their health the London County Council may well be congratulated on the result of its continuous efforts to obtain powers of control over the supply of milk which the recent report of the Royal Commission on Tuberculosis believes to be a large cause of disease and mortality. The report of the Royal Commission has amply justified the Council in its action, and there is no reason to doubt that in providing a sufficient administration for dealing with this important matter the Council will be fully supported by the ratepayers. Further powers than those which are included in the General Powers Bill are undoubtedly needed, but these will have to be obtained through a Bill introduced by the Government, which, we are sure, will not be deterred by the Council's Bill of the present year from proceeding with a comprehensive measure for dealing with a matter of so much importance to human health. In the meantime the application of the "model clauses" to London will play a useful part.

STERILE EMPYEMAS IN PNEUMONIA AND CARDIAC DISEASE WITH INTACT POLYNUCLEAR CELLS.

M. F. Widal and M. A. Philibert have shown that puriform, meningeal and pleural effusions may be due to accumulation of intact polynuclear cells and are sterile.[1] Such puriform pleural effusions, though rarer than septic effusions, deserve to be better known. At a meeting of the Académie de Médecine on July 9th M. Widal and M. Gougerot showed that they may occur during pneumonia or in case of cardiac disease with pulmonary apoplexy and be mistaken for pneumococcic pleurisy. The presence of intact polynuclear cells allows the diagnosis of sterile from septic effusions to be made. In septic effusions the leucocytes are damaged in consequence of the phagocytosis in which they are engaged. The distinction is important, because the prognosis of a sterile effusion is remarkably good. M. Widal and M. Gougerot referred to two cases of pneumonia recently observed by them in which a sterile pleural effusion with intact polynuclear cells developed. Purulent fluid was withdrawn by puncture. Its appearance was the more disquieting as the pneumonia had been severe and occurred in the course of influenza. But the presence of intact polynuclear cells allowed sterile pleurisy to be diagnosed and it regressed spontaneously. In one case defervescence occurred on the day after puncture and the signs of effusion disappeared two days later. In the second case 60 cubic centimetres of greenish-yellow, very fibrinous pus were withdrawn on the fifth day of an attack of pneumonia. Defervescence occurred on the eighth day and the effusion was rapidly absorbed. Nothing is more striking than to compare the evolution of such an effusion with a pneumococcic empyema. This was done in the case of two patients in the same ward. Both had at the end of an attack of pneumonia a small turbid effusion. Nothing in the course of the disease or in the macroscopic appearance of the effusion allowed the two cases to be distinguished, but cytological examination immediately differentiated them. The presence of intact polynuclear cells in one case allowed the rapid disappearance of the effusion to be foretold. The presence of worn-out polynuclear cells revealed the pneumococcic nature of the other, which was confirmed by culture. Defervescence did not occur at the usual time, the fever persisted, the effusion recurred and yielded only to thoracotomy. The contrast between the issues of septic and sterile effusions may be noted in the same patient. For exmple, a man had a subphrenic abscess after appendicitis and right pleural effusion developed secondarily by contiguity. The subphrenic abscess was purulent and fœtid and contained innumerable quantities of various microbes, aerobic and anaerobic. The polynuclear cells were damaged. The pleural effusion was small but puriform and turbid, and characterised by intact polynuclear cells. Microscopic examination, cultures, and inoculations gave negative results. Thus two very different collections of fluid were separated by the diaphragm. Their evolution also was very different. The pleural effusion was rapidly absorbed. The subphrenic collection increased and, in spite of operation, proved fatal. A puriform sterile effusion with intact polynuclear cells may also develop in the course of pleurisy due to a pulmonary infarct in heart disease. For example, a man, aged 44 years, was admitted into hospital on Jan. 5th, 1907, for hæmoptysis. There had been "a stitch" in the side for three days. The temperature ranged from 99·6° to 100·7° F. There was a mitral regurgitant murmur. On the 6th the patient had slight rigors, resembling some which had occurred when the pain in the side appeared. There were signs of a small left pleural effusion. The urine contained casts and six grammes of albumin per litre. Puncture of the pleura yielded a turbid, whitish, puriform, and fibrinous fluid, which contained numerous intact polynuclear cells, endothelial cells, and red corpuscles. Sterile pleurisy, consecutive to a superficial pulmonary infarct and of purely mechanical origin, was diagnosed. Rapid improvement occurred.

THE REGISTRATION OF PLUMBERS.

THE organisation existing for the registration of competent members of the trade originated, and has been sustained, through the public spirit of the Worshipful Company of Plumbers, which has spent many thousands of pounds on the registration system. It is now, however, about to be taken over by the plumbing trade. A meeting recently convened at the Guildhall to deal with this matter was attended not only by representatives of the trade from but also by representatives all parts of the United K

---

[1] THE LANCET, May 25th, 1907, p. 1446.

He was responsible for the treatment of over 4000 labour cases a year. He had hardly ever dilated the cervix for rigidity and in the few cases that he had done so he had regretted it. Referring to Dr. Galabin's case, he suggested that the patient might not have been in labour at all and that the pains described as lasting for a week had been false pains due to neurosis.

Professor **Swayne** read a paper on

Chorion-Epithelioma.

He commenced with a historical account of this disease up to date, and the cases were then reported that had been under the speaker's care. In the first of the cases the last pregnancy at full term occurred two years before the growth but ten months before a two months' amenorrhœa was followed by severe hæmorrhage and passage of clots which was probably an abortion. In the other case the symptoms occurred 17 months after the last full-time pregnancy but only ten weeks after a doubtful abortion. There were pulmonary symptoms in both cases. Pulmonary metastases, Professor Swayne thought, should not be considered as a contra-indication for radical operation. In the first case there were well-marked pulmonary symptoms and yet the patient recovered; in the second case, where the patient had similar pulmonary symptoms and died, metastases were found. Dr. J. H. Teacher's excellent photographs in the museum in Bärnfield Hall of retrograding metastases in the lung showed that one of them was converted into fibrous tissue. Hence radical operation could not be considered to be contra-indicated.

Professor **Strassmann** thought that it was very necessary to keep patients from whom hydatid moles had been removed under careful observation as in so many cases chorion-epithelioma had developed later.

Dr. **Cameron** had had two cases, in one of which pulmonary symptoms were well marked, and at the post-mortem examination retrograde changes were found in the metastases.

Dr. F. J. **McCann** (London) thought that the disease was not so rare as was generally thought. He had had five cases. He had known vaginal metastases disappear after a radical operation.

Dr. **Edge** thought that the vagina should also be removed as well as the uterus in these cases.

THURSDAY, AUGUST 1ST.

Dr. **Herbert R. Spencer** (London) opened a discussion on

The Measures to be Recommended to Secure the Earlier Recognition of Uterine Cancer.

He argued that cancer of the uterus at an early stage of its growth was curable in a large proportion of cases by vaginal operations (high amputation of the cervix and vaginal hysterectomy) with a very small immediate risk to life. In more advanced stages it might be cured by the extended abdominal operation, which, however, had a higher immediate mortality than the vaginal operations. The desirable object was to get cases of cancer in the early stages, whatever might be the operation performed. Experience in this country showed that but a small proportion of patients presented themselves to gynæcologists at the beginning of the disease and that in most of them the disease was too far advanced for even the extended abdominal operation to give a chance of cure. This unfortunate state of things was due to: (1) the patient's ignorance of the early symptoms of the disease; (2) the practitioner's delay in examining the patient who presented the early symptoms of the disease (abnormal hæmorrhage or discharge); (3) the disinclination or refusal of the patient to submit to examination; and (4) to occasional difficulty in distinguishing between benign and malignant disease of the uterus. The remedy consisted in (1) diffusion amongst women over 25 years of age of knowledge of the early symptoms of the disease and of the fact that diagnosis could only be made by means of physical examination; (2) an appeal to all general practitioners to advise examination by finger, operation, and, if necessary, by removal of growth for microscopic examination in all cases of bleeding or discharge which might be due to cancer; (3) the better education of medical students in practical gynæcology; and (4) dilatation with tents and examination of the corporeal cavity with the finger, which were not less important than the microscopical examination of curettings in the diagnosis of cancer of the corpus.

Mrs. M. A. D. **Scharlieb** (London) thought that very often the medical man if he persevered sufficiently would overcome the reluctance of many of these women to be examined. A large number of cases admitted to Mrs. Scharlieb's ward were of an inoperable nature and she thought that great harm was done by operating on women in these late cases, because their early death or the early recurrence of cancer deterred the women in their neighbourhood from seeking early advice. In a dispensary she used to attend a large number of cancer cases used to apply for treatment and operation till one of them who was far advanced in the disease was operated upon and died very soon. The result of this was that the number of cancer cases attending immediately decreased. With respect to the recurrence of cancer, even if it did recur three, four, or five years after the operation, it was worth while operating that the patient might have this increase in her life. She had lately received a letter from the husband of a patient who had died six years after the operation from recurrence, in which he expressed great gratitude for the additional years of happiness that the operation had given him.

Dr. **Galabin** thought that practitioners should be educated more thoroughly with respect to the early signs of cancer and that improvement in the number of cases sent early for operation might be expected in this way. The last case he had of cancer of the uterus was one which the general practitioner had been treating for two years as an erosion and had never had a consultation. The patient then left the medical man and her new attendant at once sent her for consultation. Dr. Galabin thought that all cases of erosions with bleeding should be sent to a consultant or examined microscopically. In cases of bleeding after the menopause where there was no evidence of cancer but where curetting did not relieve vaginal hysterectomy should be performed. Patients should also be told that hæmorrhage was not necessarily a symptom of the change of life. He thought that the great differences noted by Dr. Spencer in the results of various operations were due to the methods of operation. The best means of diffusing knowledge would be to send leaflets to nurses, midwives, and practitioners, and to give them to patients attending in the gynæcological departments of hospitals.

Professor **Strassmann** said that it had been found in Germany as the result of an appeal that at least 50 per cent. of cancer cases had not been examined by their medical attendants but that when they had applied for help they had only been given ergot or some other drug and douches. In Berlin they had sent out papers to the surrounding country. One paper was sent to the medical practitioners and an abstract of the principal symptoms of cancer was given; also a request that in any doubtful case a piece of the tissue should be cut out, put in alcohol, and sent to one of the members of the Obstetrical Society of Berlin. Lastly, it was stated that the medical man who discovered cancer early had the same merit as the operator. The second paper was sent to the midwives who in Germany attended 90 per cent. of the confinements, drawing attention to the fact that if they treated patients without sending them for examination they would be punished; that cancer began without pain and that cancer could be cured if treated early enough. He thought that in cases where there was a bad family history of cancer the members of the family should be examined occasionally. It was true that the dissemination of the pamphlet by Winter in East Prussia had caused an epidemic of "carcinoma-phobia," nevertheless he had seen many more cases after this circular had been distributed than before. Early recognition was better than a large operation.

Dr. **Walter W. H. Tate** (London) thought that most of the objections to examination were due to the fact that the reasons were not put thoroughly before the patient. He never experienced much difficulty and would like to draw particular attention to the advisability of making both a vaginal and abdominal examination. He also wished to point out that in cases of mucous polypus accompanied with bleeding after the menopause, it was not safe to put down the bleeding to the polypus. In the cases he had seen there was carcinoma of the body accompanying mucous polypus of the cervix, the bleeding really being due to the former; and in one case there had been, in addition to the mucous polypus, carcinoma of the ovaries. He thought some appeal should be sent to every practitioner to secure early recognition of these cases.

Dr. **McCann** proposed that a committee of the section should be formed to frame a leaflet dealing with the early recognition of cancer, which should be sent out to practitioners, nurses, and midwives.

above the sheep and to establish its identity with the Œstrus ovis of Linnæus, the characters of which they describe in detail in their paper. Hitherto, this fly has not been recognised as attacking man except for a few observations, such as that by S. Kirschmann in Russia. A study of the distribution of the fly in its relation to the condition produced by it in man revealed the interesting fact that this fly only attacks man in certain mountainous regions, where the number of sheep is less than the human population. In other regions where sheep are abundant man is not affected or only attacked in rare instances.

SARCOMA IN RATS.

A FORM of sarcoma occurring in rats and capable of inoculation forms the subject of an important note by Dr. Simon Flexner and Dr. J. W. Jobling of New York in the *Centralblatt für Allgemeine Pathologie und Pathologische Anatomie* of April 15th. The original tumour began in the seminal vesicle of a white rat and proved to be capable of inoculation both in white and grey rats. In the first trial inoculation succeeded in from 20 to 30 per cent. of those investigated only, but in later trials by using the more rapidly growing tumours in an early stage for inoculation successful results were obtained in from 95 to 100 per cent. Inoculation was successful whether done subcutaneously or by intramuscular or intraperitoneal methods. After inoculation the growths infiltrated surrounding tissues and in the case of the skin went on to ulceration. There was no sign of encapsulation, growth occurring at the periphery into the surrounding tissues. The nodules in the subcutaneous tissue were at first freely moveable, but later became fixed to the skin or to the muscles. Intraperitoneal inoculation usually led to multiple tumours in the omentum, the mesentery, and between the liver and the diaphragm. Sometimes the kidneys became involved in the growth; in other cases ascites was produced with a general miliary sarcomatosis of the peritoneum. A remarkable feature of this tumour was its tendency to produce widespread metastases. These were most frequent in the lungs and in the peribronchial lymphatic glands, but were also found in the ribs, intercostal muscles, the kidneys, and the heart. Rats with a primary tumour could be successfully inoculated a second time. It appears that those rats in whom a first inoculation with a less active growth has been unsuccessful often show a greater resistance to a subsequent inoculation with a more active form of the growth. Histologically the tumour appeared to be a mixed-celled sarcoma. The cells were spindle-shaped and polyhedral and a considerable number of giant cells were present. There was only a little fibrillar ground substance. In parts of some of the tumours tubular or irregularly alveolar arrangements of the cells could be recognised.

THE occasional presence of the meningococcus in the kidneys and urine of patients suffering from epidemic cerebro-spinal fever has led Dr. Pick of Berlin to recommend the systematic disinfection of the excreta in this disease. In Scotland during the week ended August 3rd, there were nine deaths from this cause registered in Glasgow, two in Leith, one in Edinburgh, one in Dundee, and one in Paisley. In Glasgow the weekly report issued on August 2nd showed that there were at that time 47 cases under treatment.

Mr. Andrew Carnegie has given £100,000 for King Edward's Hospital Fund for London. Mr. Carnegie expresses the desire that it should be used as seems best, "the more strenuously for reform the better."

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

ALTHOUGH the proceedings of the British Association for the Advancement of Science, which were commenced at Leicester on Wednesday, July 31st, were not marked by any startling announcements from any particular field of scientific research yet it must be owned that the presidential addresses and the papers read in the various sections were in general numerous and interesting and served to summarise the position of scientific progress so far as it has gone. On past occasions the subject chosen by the newly elected president for his opening address has frequently touched the fringe of medical science or related in some way or other to some branch of the healing art, a circumstance which has often called for the publication of the address in full in these columns. On the present occasion, however, the choice of President fell upon the distinguished astronomer at the Cape, Sir DAVID GILL, K.C.B., LL.D., D.Sc., F.R.S., who naturally confined his observations mainly to that department of science with which the labour of his life has chiefly been associated. The result was an exceedingly interesting review of the progress of astronomical science. He referred to the extraordinary revelations which had arisen out of the adoption of spectrographic methods, to the discovery that the nebulous light of the sky consists after all of masses of luminous gas, out of which stars or suns have been, and are being, evolved, to the amazing truth that the stars—"the crucibles of the Creator"—are alike in design, in chemical constitution, and in process of development. "The spectroscopic astronomer," said Sir David Gill, "has to thank the physicist and the chemist for the foundation of his science, but the time is coming," he added, "when the astronomer will repay the debt by wide-reaching contributions to the very fundamenta of chemical science."

The address to the Physiological Section was delivered by the president, Dr. AUGUSTUS D. WALLER, who discussed the action of anæsthetics. He referred to the attempts that have been made to determine what he thought might be designated as the physiological arithmetic of chloroform, the question of dosage. Death by chloroform he believed to be an avoidable fact which will be diminished in future years by a wider knowledge of the physiology of anæsthesia. The safe administration of chloroform consisted, in his opinion, in its continuous administration at a strength of between 1 and 2 per cent. Dr. Waller then described apparatus by means of which absolute standard mixtures of air and chloroform could be administered. Dr. FREDERIC W. HEWITT, in the course of the discussion, said that whilst he recognised the value of Dr. Waller's and Professor Vernon Harcourt's work upon this subject it was impossible to apply the method of exact percentages of chloroform in many cases and equally impossible to instruct students wholly in that method. Certain subjects required a higher percentage of chloroform than others and individuality entered largely into the matter in practice. Still he agreed that by the percentage method, aided by the practical knowledge that came of experience, the administration of anæsthetics might be robbed of its terrors.

In the Physiological Section, also, an interesting debate on the Physiological and Therapeutic Uses of Alcohol was opened by Professor A. R. CUSHNY. He observed that alcohol might sometimes increase the taste for food and encourage its digestion, but when moderation was departed from the whole of the digestive processes were disorganised. In some conditions, such as old age and debility, it might be justifiable to neglect the drawbacks of alcohol but it ought to be advised only with eyes open to the risks run and with the recognition that a drug was being prescribed. Certain investigations had shown that the abuse of alcohol lessened the resistance to invasion by pathogenic organisms but there was nothing to show that the habitual use of alcohol in small quantities or its therapeutic use had this effect, and the whole interest of the question lay in the dietetic use of alcohol as contrasted with the drunkard's abuse of it. An interesting discussion followed, in which the PRESIDENT, Sir VICTOR HORSLEY, Dr. W. H. R. RIVERS, Dr. DIXON, Mr. C. J. BOND, and Dr. REID HUNT of Washington took part.

The presidential address in the Botanical Section was delivered by Professor J. B. FARMER, M.A., F.R.S., who presented the result of his reflections on some of the progress. They must try to unravel some of the mysteries which were at present inexplicable and which seemed to be of a different order from other results of vital processes. Had there been any indications during the last year that they were nearer now than they were to the true understanding of what mind was, whether as a separate entity, as a result of brain action, or as a set of phenomena acting in a psycho-physical parallel? The public asked for illumination as to the existence of telepathy and other allied conditions. Did such communication between one mind and another exist apart from the ordinary channels of sense or was it a matter of coincidence or chance? They were now more tolerant towards the possibility of such inter-communication. Dr. J. H. Hyslop had pointed out that ethereal vibrations started by a thinker might possibly be perceived and interpreted by another. Such a psychologist as Stout could see "no sufficient reason for being peculiarly sceptical concerning communications from departed spirits," and Sir Oliver Lodge was avowedly at one with those who thought they were on the threshold of linking up material and psychical processes. No scientific experimental demonstration had, however, so far come to hand. The Church and esoteric philosophy, treating mind as a separate entity, had not advanced them one whit but there were signs of a *rapprochement* between theology and physical science. The strictures of the writer in the *Times* who reproached them with the inadequacy of their treatment of mental disorders were both inaccurate and narrow—inaccurate because never so much as lately had the influence of bodily conditions upon mental phenomena been so energetically insisted upon, and narrow because they *must* investigate mental phenomena. Just as they used the material pharmacopœia for ridding the body of lethal products, so did they use spiritualised forms of matter, otherwise mental processes, as curative agents—e.g., in hypnotic suggestion. Their conceptions as to the nature of insanity had undergone a change. They had long recognised that brain disease might exist without insanity and it now seemed as if the converse were also true. The group of toxic insanities in which were included such conditions as dementia præcox, folie circulaire, puerperal insanity, &c., might be compared with what was described as toxic neurasthenias; they might call the members of the one group insane, whilst the others were not considered so, yet there was no radical difference in the symptoms. They were confronted daily with people who were said to be not certifiably insane because a wider view was now held as to what insanity was than formerly. The question of a toxin, where it was and what was its nature came now before them. There had been a revolution in their estimation of causes and pathological processes since the study of micro-organisms was seriously undertaken. The future of psychological medicine was very hopeful and they were nearer than ever before to the rational treatment of the insane. It appeared, however, that bacteriological science was not yet sufficiently advanced for the application of general principles. For instance, a boy, aged 14 years, was recently under notice in an acute state resembling dementia præcox, due to a toxic condition of tuberculous nature, yet it would appear that injection by tuberculin would at present be of little avail. The laboratory should no longer be regarded as a fad. It was a necessity in the equipment of the modern asylum, and authorities must recognise that the splendid results achieved by Mott, Bevan Lewis, and others compelled the election of men trained in the modern school and of plenty of them. A more intelligent separation of cases must be exercised, that whilst it was right to provide for the care of the large numbers of incurable cases on a less elaborate scale, nothing must be spared on the scientific elaboration of hospital wards for acute cases. The recognition of the hospital system was the correct one, and the establishment of mental cliniques in connexion with the out-patient departments of general hospitals was in the line of true progress. The amount of sedatives and narcotics given in general practice in the early treatment of acute mental affections was surprising. This partly depended no doubt on the difficulty which confronted the general practitioner in the present state of the law, which this association and its allied societies were doing their utmost to amend. Asylum treatment had conclusively demonstrated the danger of the continuous administration of sedatives and narcotics as therapeutic agents. It had also elucidated many of the problems of the alcohol question. The need for new legislation in connexion with alcoholics was a pressing one. The question of responsibility in those for whom insanity was pleaded in criminal cases seemed to be entering on a new phase, and that the degree of responsibility was the question by which the final judgment should be ultimately determined. There was an indication that the principles laid down in Macnaughton's case were no longer those which advanced medico-legal psychology could receive. Democritus of Abdera, when he was found cutting up animals, presumably alive, said: "I do cut up these poor beasts to find out the causes of madness and melancholy, their distempers, varieties and follies, yet such proof were better made on man's body, if my kind nature would allow it." Man's body was now anatomised when he was dead and his mind when he was alive, and much was found to explain the connexion between the two, yet little was understood of the man when his body was alive but his mind was dead. More was, however, known at the present day, though it had taken 2000 years to arrive at this knowledge—verily, *ars est longa*.

Dr. F. W. MOTT (*London*) read a paper on

Alcohol and Insanity.

His experience of many years as physician to Charing Cross Hospital and as pathologist to the London County Asylums enabled him to study the effects of alcohol on the sane and the insane in the wards and in the post-mortem room. He was struck by the fact that whereas cirrhosis of the liver with ascites was relatively common in the wards and post-mortem room of the hospital, he had but once seen a case of very advanced cirrhosis with ascites at the asylums, and that was in the case of Jane Cakebread, who was convicted of drunkenness nearly 400 times before she was found incapable of taking care of herself and certified as insane. The causes of drinking were infinitely varied and bound up in the temperament and character of man. From the time of Noah wine had been used by the nations which had advanced to the highest degrees of prosperity and civilisation, and it was related in the Jewish Mashal that when Noah came to plant his vineyard Satan came to join him and asked, "What are you planting?" He replied, "A vineyard." "For what purpose?" rejoined Satan. "Its fruits," answered the patriarch, "are sweet, whether used fresh or dry, and wine is made from them which rejoices the heart." "Then shall we two work it together," observed the enemy. The effects of alcohol depended not only on the quantity and quality taken and the length of period, but upon the personality of the individual. Dr. Mott exhibited lantern slides showing the statistics relating to alcohol and insanity in the London county asylums. He observed that the percentages of admissions in which alcohol was the asserted cause of insanity varied considerably in the different asylums in the same years and in the same asylum for different years. Thus in 1902 alcohol was the assigned cause of 25·6 per cent. of the admissions to Hanwell Asylum and to Claybury Asylum, 11·2 per cent.; but in 1906 23 per cent. of the admissions to Claybury Asylum intemperance was the assigned cause, while at Colney Hatch Asylum it was 14 per cent. But when an inquiry was made into cases many were found to be inebriates or suffering from primary dementia, being subjects of an inborn tendency to mental disease. The notes showed heredity and epilepsy quite as frequently in these so-called alcoholic cases as in other forms of insanity. In the histories of these cases inherent instability in the form of neuropathies, imbecility, criminal degeneracy, epilepsy, recurrent mania, or melancholia, brain disease, and occasional head injuries existed. Frequently was revealed the fact that the patient had taken to drink on account of domestic troubles, bodily illness, loss of money, and breaking up of the home, and such conditions. The types of insanity of which alcohol was the essential cause were not so frequently seen in asylums as was generally supposed. They differed but little from cases met with in hospitals. They were delirium tremens, mania a potû, and polyneuritic psychosis, or Korsakoff's disease. No doubt many such cases were kept in infirmaries. Alcoholic insanity met with in asylums might be divided into two great groups: (1) those with a locus minoris resistentiæ in the nervous system; and (2) those in which chronic alcoholism existed with some other factor such as syphilis, microbial toxæmia, arterio-sclerosis, head injury, or organic brain disease. The subjects of Class 1 could very seldom drink sufficient alcohol to produce advanced cirrhosis, whereas Class 2, which included cases of an inborn stable mental organisation, exhibited pathological changes affecting the liver. At Charing

The number of pauper patients provided for with the sanction of the board in private dwellings on Jan. 1st, 1907, was 2774, showing an increase of 22 compared with the preceding year. Of these, 972 were boarded with guardians who are relatives and 1802 with unrelated guardians. Referring to the patients who are under private care in private dwellings Dr. John Macpherson writes: "The great majority of patients boarded with strangers could not be better taken care of if they were living with their own relations. It would be surprising that the small remuneration offered should call forth so much self-sacrifice and devotion as are often shown, were it not known that among the better guardians a patient who has lived for some time in the house comes to be regarded as one of the family." The Commissioners draw attention to the want of accommodation for the poorer class of private patients. They give a table which shows that on Jan. 1st, 1907, there were 295 private patients in district asylums formally registered as such and on May 15th, 1906 (the latest date available for the class), there were 230 patients registered as pauper patients but wholly maintained by their relatives or from other private sources, making in all 525. A table is published showing the amount of restraint and seclusion employed and it indicates what an enormous reduction has taken place in this form of treatment during the last five years. In order to furnish the Royal Commission on the Care and Control of the Feeble Minded with the information desired by it a return was obtained from all establishments for the insane in Scotland, showing among all patients admitted during the five years 1901–05 the number respectively (1) of those who had been imbecile from birth or early life; and (2) of those affected with insanity first acquired in adult life. The proportion per 100,000 of the population was 44·5 of the imbecile class and 568·0 of the acquired insanity class. An attempt was made to discover the relative proportion from the rural areas as compared with the urban districts but the number of admissions for five years proved much too small to make any conclusion on this point possible. There is an instructive statement in the report regarding the cost of building district asylums which is well worth careful perusal. The total cost of maintenance for 17,336 pauper lunatics, who were under care for longer or shorter periods durng the year 1906 in asylums, lunatic wards of poorhouses, and private dwellings, and for other expenses connected with them, was £391,108; of which £311,046 were for maintenance in asylums (including institutions for imbecile children), £19,197 were for maintenance in lunatic wards of poorhouses, £49,732 were for maintenance in private dwellings, and £11,133 were for certification, transport, and other expenses. Of this expenditure £21,577 were repaid by relatives and £115,972 were contributed from the local taxation account in terms of Section 22 of the Local Government (Scotland) Act, 1889, and of Section 2 of the Education and Local Taxation Account (Scotland) Act, 1892 The net expenditure by parish councils on the maintenance of patients was £253,559. The report contains the usual valuable tables and statistics.

THE INTERNATIONAL HOUSING CONGRESS.

The eighth meeting of the International Housing Congress was formally opened by Sir John Dickson-Poynder at Caxton Hall, Westminster, on the forenoon of August 5th. Although this is its first meeting in London the congress is not of recent origin, for it was first formed in 1889, and as we have already mentioned has met in Paris (twice), Antwerp, Bordeaux, Brussels, Düsseldorf, and Liège. It has a permanent committee, of which M. Lepreux (Belgium) is the chairman. The Governments of Austria, France, Germany, Russia, Spain, Sweden, Norway, Denmark, Belgium, Holland, Hungary, Italy, South Australia, and New Zealand have sent official delegates. The United States of America and Japan are also represented, as well as a large number of European cities, including Paris, Marseilles, and eight other places in France; Berlin, Hamburg, and 29 other places in Germany; Brussels, Antwerp, and ten other places in Belgium; and Amsterdam, Rotterdam, and four other places in Holland. The United Kingdom is represented by the Local Government Boards of England, Scotland, and Ireland, by several county councils and London borough councils, and by a number of provincial towns. All the papers read before the congress were printed in English, French, and German.

Sir John Dickson-Poynder in his introductory remarks spoke of the importance of the question and the difficulties with which it was surrounded; he said that it was common to all industrial countries and that international conferences were valuable means of suggesting remedies for the existing evils.

Mr. John Burns, President of the Local Government Board of England, welcomed the Congress on behalf of the Prime Minister and the British Government. He said that in London all types of houses, all varieties of architecture, and all methods of building were to be seen. In every country, old and new, the people were being rapidly urbanised, and if the urbanisation of the poor were not controlled devitalisation of the people must occur. Improvements were being made in London, and in fact the progress made in the last decade was greater than in the previous century. London, however, was not yet what it should be. The proportion of overcrowded population, living more than two in a room, was: in London, 1 in 7; in Leeds, 1 in 10; in Sheffield, 1 in 12. Nevertheless, the death-rate in this country was roughly the lowest in the world, and with regard to housing there were five persons per house in England, where they lived in cottages; 10 persons per house in London, where they lived in houses; 20 per house in New York, where they lived in tenements; and 26 in Paris and 46 in Berlin, where they lived in barracks. In New York, where he had recently been, notwithstanding the alleged superiority of comfort and wealth, there were 350,000 dark interior rooms, and 2,300,000 persons living in 82,000 tenement houses. With regard to reform they must not be too peremptory or too uniform in dealing with different conditions. The class affected by the housing difficulty were not the rich or the middle classes, or even the artisan class in whose houses great improvement had been effected along with improved knowledge and increased sobriety. The difficult class was that of the unskilled labourer, whose home was a place to be away from and live out of, a noisy rendezvous provoking appetites which found solace in the public-house. Where casual labour was endemic poverty was epidemic. But as the causes were multiple, so the remedies must be multiple, the essential condition being to raise the wage of the unskilled labourer, who must also have improved education and be brought up to the standard of the artisan. Mr. Burns contrasted the poor man's home with the housing of criminals, paupers, and lunatics, on whom as much was spent per bed as reformers asked for to provide a whole house for a family. After referring to the importance of traction and the work of the London County Council, especially in the provision of trams, he warned them not to be too enthusiastic about any particular remedy. The evils were multiple—there were the rush to the towns, the immobility of skilled labour, drinking habits created and perpetuated by slum life, and female labour. With regard to the rural exodus he believed that a rural return was going on, that the excitement of town life had been found out, and the benefit of fresh air recognised. In conclusion, he strongly deprecated the view that in finding better homes for the people the State should do more than it had been doing, the municipality less, and the individual still less. His opinion, on the contrary, was that individual action was an essential requisite for success.

The Mayor of Westminster also delivered a short address of welcome, after which a vote of thanks to Mr. Burns and the other speakers was passed, on the motion of M. Lepreux, seconded by Signor Magaldi (Italy).

In the afternoon Alderman William Thompson delivered his presidential address. He said that there was a general agreement of opinion to the effect that unhealthy dwellings and slums should be improved or destroyed at the expense of somebody. It was also generally held that the public up to now had had to pay too much for getting rid of the dangers, so often caused by neglect or selfishness of private individuals or of the owners of such property. The new housing accommodation was insufficient in quantity, inferior in quality, or, in many vital respects, unsuitable in character, the place that should be occupied by cottages, for which there was a great demand, being filled by a kind of spurious villa which was not really wanted. It was therefore necessary to encourage private owners and local authorities by means of one kind or another to increase, improve, and vary the supply of new and suitable dwellings. Contrary to many prevailing notions, municipal building in towns had not been followed by a progress. They must try to unravel some of the mysteries which were at present inexplicable and which seemed to be of a different order from other results of vital processes. Had there been any indications during the last year that they were nearer now than they were to the true understanding of what mind was, whether as a separate entity, as a result of brain action, or as a set of phenomena acting in a psycho-physical parallel? The public asked for illumination as to the existence of telepathy and other allied conditions. Did such communication between one mind and another exist apart from the ordinary channels of sense or was it a matter of coincidence or chance? They were now more tolerant towards the possibility of such inter-communication. Dr. J. H. Hyslop had pointed out that ethereal vibrations started by a thinker might possibly be perceived and interpreted by another. Such a psychologist as Stout could see "no sufficient reason for being peculiarly sceptical concerning communications from departed spirits," and Sir Oliver Lodge was avowedly at one with those who thought they were on the threshold of linking up material and psychical processes. No scientific experimental demonstration had, however, so far come to hand. The Church and esoteric philosophy, treating mind as a separate entity, had not advanced them one whit but there were signs of a *rapprochement* between theology and physical science. The strictures of the writer in the *Times* who reproached them with the inadequacy of their treatment of mental disorders were both inaccurate and narrow—inaccurate because never so much as lately had the influence of bodily conditions upon mental phenomena been so energetically insisted upon; and narrow because they *must* investigate mental phenomena. Just as they used the material pharmacopœia for ridding the body of lethal products, so did they use spiritualised forms of matter, otherwise mental processes, as curative agents—e.g., in hypnotic suggestion. Their conceptions as to the nature of insanity had undergone a change. They had long recognised that brain disease might exist without insanity and it now seemed as if the converse were also true. The group of toxic insanities in which were included such conditions as dementia præcox, *folie circulaire*, puerperal insanity, &c., might be compared with what was described as toxic neurasthenia; they might call the members of the one group insane, whilst the others were not considered so; yet there was no radical difference in the symptoms. They were confronted daily with people who were said to be not certifiably insane because a wider view was now held as to what insanity was than formerly. The question of a toxin, where it was and what was its nature came now before them. There had been a revolution in their estimation of causes and pathological processes since the study of micro-organisms was seriously undertaken. The future of psychological medicine was very hopeful and they were nearer than ever before to the rational treatment of the insane. It appeared, however, that bacteriological science was not yet sufficiently advanced for the application of general principles. For instance, a boy, aged 14 years, was recently under notice in an acute state resembling dementia præcox, due to a toxic condition of tuberculous nature, yet it would appear that injection by tuberculin would at present be of little avail. The laboratory should no longer be regarded as a fad. It was a necessity in the equipment of the modern asylum, and authorities must recognise that the splendid results achieved by Mott, Bevan Lewis, and others compelled the election of men trained in the modern school and of plenty of them. A more intelligent separation of cases must be exercised, that whilst it was right to provide for the care of the large numbers of incurable cases on a less elaborate scale, nothing must be spared on the scientific elaboration of hospital wards for acute cases. The recognition of the hospital system was the correct one, and the establishment of mental cliniques in connexion with the out-patient departments of general hospitals was in the line of true progress. The amount of sedatives and narcotics given in general practice in the early treatment of acute mental affections was surprising. This partly depended no doubt on the difficulty which confronted the general practitioner in the present state of the law, which this association and its allied societies were doing their utmost to amend. Asylum treatment had conclusively demonstrated the danger of the continuous administration of sedatives and narcotics as therapeutic agents. It had also elucidated many of the problems of the alcohol question. The need for new legislation in connexion with alcoholics was a pressing one. The question of responsibility in those for whom insanity was pleaded in criminal cases seemed to be entering on a new phase, and that the degree of responsibility was the question by which the final judgment should be ultimately determined. There was an indication that the principles laid down in Macnaughton's case were no longer those which advanced medico-legal psychology could receive. Democritus of Abdera, when he was found cutting up animals, presumably alive, said: "I do cut up these poor beasts to find out the causes of madness and melancholy, their distempers, varieties and follies, yet such proof were better made on man's body, if my kind nature would allow it." Man's body was now anatomised when he was dead and his mind when he was alive, and much was found to explain the connexion between the two, yet little was understood of the man when his body was alive but his mind was dead. More was, however, known at the present day, though it had taken 2000 years to arrive at this knowledge—verily, *ars est longa*.

Dr. F. W. MOTT (London) read a paper on

Alcohol and Insanity.

His experience of many years as physician to Charing Cross Hospital and as pathologist to the London County Asylums enabled him to study the effects of alcohol on the sane and the insane in the wards and in the post-mortem room. He was struck by the fact that whereas cirrhosis of the liver with ascites was relatively common in the wards and post-mortem room of the hospital, he had but once seen a case of very advanced cirrhosis with ascites at the asylums, and that was in the case of Jane Cakebread, who was convicted of drunkenness nearly 400 times before she was found incapable of taking care of herself and certified as insane. The causes of drinking were infinitely varied and bound up in the temperament and character of man. From the time of Noah wine had been used by the nations which had advanced to the highest degrees of prosperity and civilisation, and it was related in the Jewish Mashal that when Noah came to plant his vineyard Satan came to join him and asked, "What are you planting?" He replied, "A vineyard." "For what purpose?" rejoined Satan. "Its fruits," answered the patriarch, "are sweet, whether used fresh or dry, and wine is made from them which rejoices the heart." "Then shall we two work it together," observed the enemy. The effects of alcohol depended not only on the quantity and quality taken and the length of period, but upon the personality of the individual. Dr. Mott exhibited lantern slides showing the statistics relating to alcohol and insanity in the London county asylums. He observed that the percentages of admissions in which alcohol was the asserted cause of insanity varied considerably in the different asylums in the same years and in the same asylum for different years. Thus in 1902 alcohol was the assigned cause of 25·6 per cent. of the admissions to Hanwell Asylum and to Claybury Asylum, 11·2 per cent.; but in 1906 28 per cent. of the admissions to Claybury Asylum intemperance was the assigned cause, while at Colney Hatch Asylum it was 14 per cent. But when an inquiry was made into cases many were found to be inebriates or suffering from primary dementia, being subjects of an inborn tendency to mental disease. The notes showed heredity and epilepsy quite as frequently in these so-called alcoholic cases as in other forms of insanity. In the histories of these cases inherent instability in the form of neuropathies, imbecility, criminal degeneracy, epilepsy, recurrent mania, or melancholia, brain disease, and occasional head injuries existed. Frequently was revealed the fact that the patient had taken to drink on account of domestic troubles, bodily illness, loss of money, and breaking up of the home, and such conditions. The types of insanity of which alcohol was the essential cause were not so frequently seen in asylums as was generally supposed. They differed but little from cases met with in hospitals. They were delirium tremens, mania a potu, and polyneuritic psychosis, or Korsakoff's disease. No doubt many such cases were kept in infirmaries. Alcoholic insanity met with in asylums might be divided into two great groups: (1) those with a locus minoris resistentiae in the nervous system; and (2) those in which chronic alcoholism existed with some other factor such as syphilis, microbial toxæmia, arterio-sclerosis, head injury, or organic brain disease. The subjects of Class 1 could very seldom drink sufficient alcohol to produce advanced cirrhosis, whereas Class 2, which included cases of an inborn stable mental organisation, exhibited pathological changes affecting the liver. At Charing association some of the papers already admitted, but in this rested the power and opportunity of making a worthy press and of rendering it a privilege and an honour to belong to the German Association of the Medical Press. The question as to the legality of a black list had been raised. In Germany it was not thought illegal if it could be proved that it was for the public good and not due to any personal animosity. However, one of the black-listed men had taken legal action; therefore a verdict would soon be rendered which would clear up this somewhat doubtful question. Among other works attempted an effort had been made to regulate spelling and rules had been established to govern newspaper controversies. The opener of the controversy had the right to conclude but it was not always easy to ascertain who had begun the controversy. In that case the editor had the right to decide. Again, there was the question of rejecting certain classes of advertisements, and the German papers were all being brought into line, so that they should each act in the same manner. Thus recently a remedy was to be advertised with exaggerated descriptions of its efficacy. Therefore all the papers refused to insert the advertisement. The manufacturer had then to modify his tone, and the advertisement was only inserted when all exaggerated and false statements had been withdrawn. Professor Posner concluded by saying that the committee must meet again before the Budapest Medical Congress and, on behalf of the Austro-German press, invited the committee to come to Berlin at a date to be fixed according to circumstances.

Dr. DEJACE, speaking on behalf of the Belgian Association of the Medical Press, said that they had also been engaged in raising the moral tone of the medical press. In 1898 a law sanctioning professional associations was passed and since then they had attempted to group the medical profession. The difficulty was to find disciplinary powers, for the law was very severe against boycotting. In Belgium they had better prospects of success by creating advantages than by inflicting penalties. Thus, they had organised at reduced cost scientific excursions to visit foreign countries. In regard to gratuitous papers, these were not published in Belgium, but a great many came from abroad. In Belgium the sale of their medical papers only just paid for the printing. If the contributors were paid this could only be done from the product of the advertisements, and the papers that were distributed gratuitously did much mischief.

From Norway and Great Britain there was nothing new to report and the committee then proceeded to consider the financial situation of the International Association. Dr. DAWSON WILLIAMS as international treasurer presented his accounts and books, from which it appeared that some of the smaller nationalities had not yet paid their subscriptions. This subscription amounts to 20 francs per annum per member allowed on the international committee. Thus Great Britain, being represented by three members, pays 60 francs, and Belgium, as a smaller country, has two members and therefore pays only 40 francs. If some of the subscriptions due have not yet come in it may as an offset be noted that, as yet, no money has been spent. The general secretary, Dr. Blondel, has carried on the international correspondence for now seven years at his own expense but refused to make any change and declared that he had kept no account. It was, however, determined that in future his office expenses should be reimbursed. It was also decided to issue a pamphlet giving an account of all the medical press associations which formed part of the International Association. The sitting then adjourned for lunch.

(To be continued.)

THE SECOND INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

THIS Congress was opened by the Earl of Crewe, Lord President of the Council, on August 5th at the University of London. A very large attendance included delegates from all the countries of Europe, the colonies, North and South America, and from various bodies in Great Britain. Lord Crewe presided and was supported by Sir Lauder Brunton (the President of the Congress), Lord Londonderry, Lord Fitzmaurice (Under Secretary for Foreign Affairs), Lord Cheylesmore, Sir Robert Morant (Secretary to the Board of Education), the Greek Minister, Sir Norman Lockyer, Sir James Crichton-Browne, Professor Griesbach (Germany), Dr. L. H. Gulick (United States), Sir Alexander Pedl (India), Dr. A. Mathieu (France), Sir Philip Jones (New Sout Wales), and Dr. L. Burgerstein (Austria).

Lord CREWE, who was enthusiastically received, ro formally to open the Congress. He said that the first dut he had to perform in connexion with the opening ceremon was a very agreeable one. He had a gracious command fro the King to express to them the interest with which H Majesty regarded the subjects with which that congress wa concerned and his regret that owing to his enforced absenc from London he was unable to receive those who were t attend the Congress. He was also privileged, on behalf of th Government, to offer them all a hearty welcome It was no in a strict sense an official conference. He regretted tha it had not been possible to hold the Congress at a tim of year when London was less deserted than it was a present. This was the date most convenient to most of it members, and they only expressed that regret in the fea that the stay of those who had come from abroad, fron the colonies, and from different parts of the Empir might be less agreeable than if the Congress had bee held at some other time of the year. The scope of the dis cussions at the Congress was exceedingly wide. It seemed to him that the subject divided itself into two main branches. The first was exceedingly obvious and necessary, but so far as this country was concerned its usefulness must be regarded as limited. He alluded to the whole question of hygiene s far as it was concerned with school buildings and schoo sanitation. On the second branch of the subject—namely, the health of the children themselves and the manner in which the instruction given them could be used to their best advantage—foremost in the minds of all there necessarily came the question of medical inspection. That was a subject on which there might exist legitimate differences of opinion as to the machinery, but as to the importance of the subject itself there could not be two opinions. Classification might be said to be the grammar of science, and in applying the science of hygiene to the question of education they were beginning to see how necessary it was to classify it. To a certain extent, of course, in this country, though they might be described as in some degree backward, that had already been done. Where children were obviously mentally deficient they had already set them apart but they were beginning to understand that classification must go a great deal further. They saw that there were many children, he feared a large number, who were not blind but who could only see imperfectly, a great number who were not deaf but who heard imperfectly, and many more still who suffered from congenital defects connected with breathing which, if not dealt with early when they could be simply dealt with, might have the most disastrous effects upon their future lives They were also beginning to understand the great importance of applying the arts of dentistry to the children in their elementary schools at an early age. All these matters they desired to deal with on grounds of humanity in the first place but they were also deeply impressed by the fact that to deal with them in a satisfactory way was also a very real piece of national economy. Where defective children were subjected to the discipline of the school, and to what for them was the overwork of the ordinary curriculum of the school, they were likely to become less good citizens and a greater danger to the State than would have been the case if they had been left alone altogether. That was what they desired to correct and what they believed the Congress could do much to instruct them about. Then there was the further branch of their discussions as to how to make healthy children healthier still by means of physical training. They learnt that, however good physical training might be in itself, it was useless to apply it to defective children or to underfed children. They were about to undertake arduous labours and he hoped that the result of their meeting might have the best possible effects. It must be a good thing for those belonging to different nations and used to different systems to interchange ideas and to engage in a most honourable and friendly rivalry as to which nation and which system could best carry out the objects they all had in view. He hoped, therefore, that their deliberations would do much to advance the knowledge of school hygiene and to remove what they must all regard as having been a serious blot on the civilisation of the world.

Lord LONDONDERRY said that it was as President of the Board of Education that he was closely associated with that and slept the greater part of the day. Since she had been under treatment menstruation had become established and improvement had ensued. In the second case, that of a girl, aged 17 years, who had been bright at school, nothing odd had been noticed until she menstruated at the age of 15 years, since which time she had been strange at every period. She became excitable and talkative and quite changed from her ordinary retiring disposition. The subject of the third case, a young man, aged 21 years, had always been feeble-minded, but for the first week in every month he was much worse—he would then become excited and would scream and imagine that he saw things in the room. These attacks came on and cleared up suddenly. All three cases had benefited greatly from anti-epileptic treatment, the attacks becoming much less frequent.

The PRESIDENT referred to the difficulty of classification in mental disease and believed that loss of control was the principal element in all cases of insanity. He cited Dr. Wigan's book on double consciousness written over 40 years ago as closely bearing on the cases quoted.

Dr. YELLOWLEES remarked on Dr. Mercier's paradoxes and said that he could hardly call any of the cases examples of dementia.

Dr. WHITE asked whether the attacks of so-called dementia occurred at regular intervals.

Dr. HURD questioned the advantage of using the term "dementia" to describe the conditions present.

Dr. R. H. COLE (London) suggested that "stupor" was frequently used as a term for recoverable forms of so-called dementia.

Dr. R. CUNYNGHAM BROWN (Parkhurst) asked whether amnesia was present in any of the cases.

Dr. ROBERTSON preferred the term "periodic mental deterioration" as used by Spitzka for the cases in question.

Dr. MACDONALD agreed entirely with Dr. Mercier in the use of the term "dementia."

Dr. MERCIER replied briefly.

DENTAL SURGERY.

WEDNESDAY, JULY 31ST.

Mr. J. MCKNO ACKLAND (Exeter), the President of the section, delivered his opening address. He briefly reviewed the past work of the section and indicated some of the problems which still required elucidation. He then called upon

Dr. G. F. STILL (London) to open a discussion on

The Causes, Defects, and Treatment of Dental Disease in Children.

Dr. Still discussed the relationship of dental caries, abdominal pain, lymphadenitis, and certain habit spasms.

Mr. EDMUND OWEN (London), in continuing the discussion from the point of view of a general surgeon, emphasised the deplorable dental condition of children associated with artificial feeding, particularly the early use of soft food.

Mr. J. G. TURNER (London) continued the discussion from the point of the pathology of deformities of the enamel of children's teeth, illustrating his observations by lantern slides.

The discussion was then taken up by Dr. E. CAUTLEY (London) and was continued by Dr. G. A. SUTHERLAND (London), Mr. KENNETH W. GOADBY (London), Mr. R. DENISON PEDLEY (London), Mr. W. R. ACKLAND (Exeter), and Mr. C. E. WALLIS (London).

On the motion of the PRESIDENT the discussion was adjourned until Thursday, August 1st.

The PRESIDENT moved that a telegram of congratulation should be sent to the Stomatological Association of France which was holding its first meeting in Paris on August 1st. The motion was carried by acclamation.

TROPICAL DISEASES.

WEDNESDAY, JULY 31ST.

Mr. JAMES CANTLIE (London), the President of the Section, gave an opening address in which he reviewed the

Changes in the Aspect of the Study of Tropical Diseases

during the two years since the Section last met. He stated that during the last quarter of the nineteenth century the study of bacteria usurped their attention, but the advent of the twentieth century found the protozoa assuming a foremost position in tropical pathology. In the schools of tropical medicine in London and Liverpool lectureships on protozoology, parasitology, helminthology, and entomology had been established and were found a necessary adjunct to the study of diseases in the tropics. These schools would prove but the pioneers in regard to this new departure; the general medical schools throughout the empire would have to follow the example set, and at an early date, if they were to fulfil their purpose efficiently. There was a risk in appointing men other than medical men to these lectureships, as the practical side of the teaching would be thereby endangered and the purely scientific aspect of the study elevated to a position beyond practical needs. Mr. Cantlie urged the necessity of lectureships on geographical pathology to encourage a more intimate study of the geographical distribution of the animals by which man became infected by disease. He stated that there was scarcely any of the domestic animals or of the house, body, or bed pests which were not found to be concerned in the transmission of disease to man. They had known for a long time that the dog communicated hydrophobia and hydatids to man, that the horse infected man with glanders, and the pig gave trichina; but during recent years the list had extended. The tuberculosis of cattle and man was believed to be co-related; Malta fever was conveyed to man by goat's milk infected with the micrococcus melitensis; malaria, filaria, and yellow fever were caused by the bites of infected mosquitoes; rats by their infected fleas conveyed plague to man; trypanosomes were met with in many animals and found their way to man by blood-sucking flies; piroplasmata were transmitted from one animal to another, and possibly to man by ticks. Fresh water cyclops communicated the guinea worm; the bed-bug, the louse, the cockroach, and even the house-fly were all known as intermediary hosts or as the transmitters of disease to man. In fact, there was scarcely an animal, whether it be a domestic animal or one belonging to the group they were wont to style verminous, that was not capable of infecting man. This was a new feature in pathology; the dangers from these animals had long been suspected but only now was scientific proof forthcoming. The abhorrence of vermin was inherited: it was out of all proportion to the direct trouble or inconvenience these animals caused and was no doubt due to the knowledge of their forefathers, empiric it might be, and more or less allied to superstition, but none the less practical, that, in driving away or exterminating these parasites wholesale, not only the pests themselves, but the diseases they communicated were being got rid of as well. There could be no other explanation of the extraordinary intolerance of mankind towards these so-called vermin. Mr. Cantlie then reviewed some of the important work done recently in tropical diseases. Malta fever had been shown to be due to imbibing goat's milk infected by the micrococcus militensis. Sleeping sickness had been proved to be caused by the bite of a tsetse-fly infected with trypanosomes. The association between blackwater fever and the exhibition of quinine noted by some observers was largely refuted, inasmuch as returns showed that blackwater fever occurred more often in persons who did not take quinine as a prophylactic than in those who did. The fresh water cyclops had been well-nigh conclusively proved to be the intermediary host of the guinea-worm, and Dr. Leiper's observation that whilst the cyclops was digested in an acid solution the embryos of the guinea-worm were stimulated to greater activity seemed to show that the embryos enter the human body by way of the mouth and stomach. Beri-beri had recently been studied by Dr. W. L. Braddon, who stated that when rice of the "cured" or fresh sort was eaten beri-beri did not result, but when "uncured" rice was consumed for any length of time beri-beri might attack people of any nationality. The rat-flea theory of plague infection had been recently conclusively proved. Their knowledge of filaria perstans and of filaria Philippinensis had been added to by Dr. Creighton Wellman, Dr. P. M. Ashburn, and Dr. C. F. Craig respectively. Dengue fever was held by Dr. Ashburn and Dr. Craig to be communicated by the Culex fatigans in the Philippines. Schistosomes had gained in importance as factors in disease and the differentiation between the terminal spined ovum and the lateral spined ovum anticipated by Manson had now been confirmed, the former, the Schistosomum (bilharzia) hæmatobium, being essentially the parasite of the genito-urinary tract, the latter, the Schistosomum mansoni (Sambon), inhabiting the alimentary tract. The greatest additions to their knowledge, however, were found in regard contended that *education was the adjustment during its plastic period of the organism to its environment.*

The Medical and Hygienic Inspection of Schools formed a section by itself and Dr. G. ANSCHUTZ (*Buenos Ayres*) showed how Argentina had put public schools under medical inspection and insisted on proper buildings, baths, cleanliness, and vaccination, with segregation of defective children and *country schools for debilitated scholars.* Dr. A. S. ARKLE (Liverpool) communicated a paper on the *Physique* of Elementary School Children in Liverpool, and Dr. JANET CAMPBELL gave details of the *medical supervision* of the London County Council *secondary schools.* Dr. J. J. CRONIN (New York), in a paper on Medical Treatment at School in its Social, Economic, and Professional Aspects, urged that medical treatment at school could be justified not *only by results* but also on the grounds of economic gain. Dr. A. C. E. GRAY (London) in a *communication* on Medical Treatment at School and its Relation *to the Family Doctor,* said that it was necessary *to procure the coöperation of* the parents. Dr. J. A. *HAYWARD (Wimbledon)* gave his views on the *coöperation of doctor, teacher,* and nurse in school inspection. *Dr. FRANCES IVENS stated* the results of an examination *of 1000* children in *relation to* ear disease in East London *school children. Dr.* G. JORNELL (Sweden) explained how secondary schools in Sweden had medical inspectors with *well-defined* duties. Dr. H. M. RICHARDS (Croydon) described the organised medical supervision of school children as carried out at Croydon and Dr. S. THIERSCH detailed the method of examining children on admission to the public school in Leipsic.

In the section on Instruction in *Hygiene for Teachers* and Scholars Professor R. CATON (Liverpool) took up the question of the teaching of hygiene in *primary schools* and pointed out how the object-lessons too often witnessed by the children of the results of alcoholism might be turned to good if they were taught the physiological effect of alcohol upon the animal *body.* Professor C. C. DOUGLAS (Glasgow) showed how the practical training of teachers in school *hygiene* should be cut down to the consideration of the effects of *school-life* on the child. Dr. H. R. KENWOOD (London) in a paper on Hygiene as a School Subject in *Elementary Schools, contended* that it was unnecessary to teach *the mechanism of respiration* in order *to* inculcate the value of fresh air. *He advocated the* simplest hygienic training Dr. A. BROWN RITCHIE (Manchester) said that in *Manchester the knowledge* of hygiene acquired by the *teachers* was already bearing fruit.—Dr. C. E. SHELLY (*Haileybury*) *contributed* a paper on the Teaching *of Hygiene* in *Secondary* Schools.

Dr. H. L. P. HULBERT (Manchester) in the section on Out-of-School Hygiene gave some interesting facts concerning the Manchester country school for town children. In the section on Special Schools for Feeble-minded and Exceptional Children Dr. MAY DICKINSON BERRY read a paper on the Family History and Home Surroundings of Children in the London Centres for the Mentally Helpless, and Dr. R. C. ELMSLIE contributed a communication on the Classes of Physically Defective Children for whom Instruction in Special Schools is Necessary. Dr. P. HERTZ (Copenhagen) described the conditions of health of the backward children in the elementary schools of Copenhagen, and Mr. E. MUIRHEAD LITTLE read a paper on a Hospital School for Cripples. Dr. G. E. SHUTTLEWORTH dealt with the Differentiation of Mentally Deficient Children and Dr. ALAN MCDOUGALL (Alderley Edge) discussed the Treatment of Children in Epileptic Schools.

In the section dealing with Special Schools for *Blind, Deaf,* and Dumb Children Dr. A. BRONNER (Bradford) read a paper on the Definition of Blindness in Children, its *Causes* and Prevention. Mr. N. BISHOP HARMAN (London) communicated his views on the Medical Characteristics associated with Blindness of Varying Causation and their *relation to* Training.

In the section on Hygiene of Residential Schools *Dr.* EDMUND CAUTLEY (London) discussed the question of diet in residential schools and commented on the importance to be attached to the refusal of food as a sign of illness or that the diet was unsatisfactory. In the section on the School Building and its Equipment Dr. J. HAMMAR (Stockholm) gave a short account of investigations in the school hygiene of the board schools of Stockholm and *Dr.* C. PORTER (Leeds), in a paper on sanitary appliances for *schools,* formulated his objections to troughs and *described* the *wash-down* closets in the West Leeds high school. *An interesting* communication was received from Dr. T. WOOD (*Leith*) on the characteristics of the ideal desk for children.

Sir Shirley F. Murphy was retained in the *House* of Commons and so was unable *to be present in time* to deliver his opening *remarks* on the work of the Seventh Section. A paper was read for him by *Dr.* H. T. BULSTRODE, who also presided over the section, in which Sir Shirley Murphy set forth

The Intimate Relations between Infectious Disease in the Schools and among the Population at Large.

He said that in striving to check *the latter* information *gathered* in *the schools* would be most useful. For this and other reasons the same authority should have in hand both services. From *1892–97* some *15,000* children lost their lives from diphtheria in the London schools and he thought better measures would have been taken if there had been but one instead of two administrations at work. School attendance concerned the general health, for it meant an increase of infectious disease. Thus the statistics of the ten years 1895–1904 showed that there were more scarlet fever and diphtheria in London during the months when the schools were open. The figures given were *27·6 per cent.* less scarlet fever and 23·3 per cent. less diphtheria during the holiday season, as compared to the two months before and after the holidays. The principal *cause of* the *spread of* disease was the mild and unsuspected "carrier" cases as they were called. It was the teachers rather *than the* medical inspectors who could detect such cases. Still, it did not seem that many children in London suffered from scarlet fever—only 68·8 per 1000 children who had reached the age of ten years in 1906. This apparently indicated that many cases were not notified, perhaps not even detected. In regard to tuberculosis Sir Shirley Murphy said: "If I may hazard a conjecture as to the trend of *evidence* concerning the *conditions* which cause this disease, I might say that infection by ingestion must increasingly be regarded as the largest factor in tuberculosis." In conclusion, he urged that the health of the population at all ages depended on the efficacy of *school* inspection. "Attendance at schools gives opportunity *for* the health officer to concern himself with the *personal* hygiene *of* a considerable section of the community, and further, to control, at any rate in some degree, the prevalence in the total population of the class of maladies which *come* under the cognisance of this section."

Dr. JAMES NIVEN, medical officer of health of *Manchester,* read the next paper. He dealt with diphtheria in *schools and* gave *figures to show* that from 1901–05 the *diminution of* the death-rate at school ages was less than at *other ages.* The incidence of diphtheria had been so altered as to fall more than formerly on children at *the school* age. This did not mean that the total number of cases at all *ages had increased.* It is true that there were fewer cases known to occur at holiday *times* but there was then more healthy outdoor exercise and also a greater temptation to conceal cases so *as not to spoil* the holidays. The larger number of cases of diphtheria occurred among children three and four years old, that *is to say,* before the school age, but they were in constant contact with *older* children who frequented schools. *Then* there was a great decrease at the age of six years, *due perhaps* to widespread establishment of immunity. In *Manchester* in 1906, out of 109,765 school children giving an average attendance of 90 per cent. there were only 177 cases of diphtheria. There were *occasional* "*flare ups*" in school because a child showing no clinical symptoms would produce copious *discharges* rich in diphtheria bacilli. *It was* remarkable that the poorest *districts were* not the greatest sufferers. In North Manchester the death-rate from diphtheria was two or three times *as great as* in the Manchester township, yet the latter possessed the poorest schools. The outbreaks seemed to depend *on* the aggregation of children *not* yet immunised rather than *on* sanitary *or* economic conditions. *In the* poorer quarters a low type *of bacilli* seemed to confer immunity. *The* "short" or "*suspicious*" bacillus was frequently a true *diphtheria* bacillus and Dr. Niven maintained that "the facts seem to point to a widespread production of immunity, especially in the poorest districts, through bacilli of comparatively low *virulence.*" On the other hand, they often had true diphtheria where the *bacillus had not* been found, therefore clinical *diagnosis* still remained necessary. But to *provide all these services* a very large staff was required, such as had been provided and very painful and there developed a blood-stained hydrocele. Suppuration, gangrene, or atrophy might result. The twist occurred inside the tunica vaginalis and there was commonly a persistent mesorchium. He had met with every degree of severity from a half turn to four complete revolutions. He recommended removal when the testicle as imperfectly descended and complicated by hernia. The gan was then functionless and repetitions were avoided.

Mr. W. E. Dixon (Lowestoft) briefly reviewed the subject of gano-therapy, alluding to Brown-Séquard's original experi- nt with the fresh testicular extract of the dog, which tored him to youth and vital energy. Various results had n obtained but they were all worthless scientifically, since y ignored psychical effects and those due to the action of leo-albumins. The spermine of the Russian, Dr. Poel, under the same objection. There were now known three nite alkaloidal bodies—adrenalin, secretin (from the enum), and thyroidin—of which the first two had been ined in crystalline form. The corresponding body from testis had not yet been isolated but he prophesied it l one day be separated in crystalline condition. It l be more universal in effect than the preceding which ly applied to all vertebrates, since the testicular uce would apply to the invertebrates likewise. He he case of the hermit crab in which a parasite (pelto- inclosed and destroyed the male sexual organs, ally castrating the animal, which then became in- uishable from a female, even to the presence of ova in sidue of the testicle, though such a corresponding did not occur when the female was affected. ernal secretion was supplied by the interstitial cells t by the spermatic gland tissue. When the spermatic of an animal were cut this latter atrophied and the of procreation ceased, but the interstitial tissue rophied and the sex characteristics remained un- ed. In embryo pigs this interstitial tissue occurred in males. In man removal of the testicles before y prevented the development of sex characteristics. ticle might be functional in regard to this internal ion, though not for procreation. Hypertrophy of the renal gland was associated with precocious sexual de- ment in children and atrophy with absence of secondary haracteristics, showing a close relation between the al bodies and sexual development. A substance closely to adrenalin occurred in the placenta, attaining a maxi- at term, and brought about contraction of the uterus and l-vessels after delivery and probably precipitated labour.

Mr. W. McAdam Eccles (London), speaking of imperfect ent of both testicles, said that the interstitial cells were developed in 80 per cent of the cases and were present ore birth but to a less extent. In those animals in which porary descent of the testicles occurred these interstitial ls were only present at such times corresponding to the ting season, being altogether absent at others. He ought, therefore, that the testicles should be preserved to individual, even when imperfectly developed, by returning d fixing them in the abdomen. It was disastrous to the tis to fix it in the scrotum. One could count on the gers of one hand the cases in English literature where increase in size had occurred after such a proceeding. The mesorchium was present in all such undeveloped testes. In cretins the testicles were always undescended; it would be interesting to know the condition of the suprarenal bodies them. How was it that undeveloped and undescended testicles only occurred in the human subject?

Mr. G. H. Edington (Glasgow) said that tubercle of the processus vaginalis was sometimes mistaken for disease of the testicle. It presented nodular masses at the lower end of the spermatic cord, and in one case where this was dissected out and removed similar masses on the opposite side disappeared spontaneously, but a year after tuberculous dactylitis occurred in the same patient. A second case was treated satisfactorily by the local application of 10 per cent. *iodoform* in glycerine. Another disease affecting this region was acute vaginalitis. In one case of this kind pus was evacuated after five days' fever containing the pneumococcus, and in another a similar procedure was carried out after three days. The attacks bore some resemblance to strangulation of the testis. In some instances of misplaced testis the organ was extruded upwards and outwards from the inguinal canal much in the same direction as a hernia through the femoral ring. Sometimes the epididymis passed off from the inferior pole of the testis accompanied by the vessels, while the processus vaginalis lay above and between.

Mr. J. P. Lockhart Mummery (London) was opposed to syphilis being a common cause of testicular enlargement in infants as compared with tubercle. Tuberculous disease of the processus vaginalis was part of a general tuberculous peritonitis, but the condition usually subsided after laparotomy. He held the same view as had already been expressed as to not removing the testis but fixing it in the abdomen. It did not always develop but the younger the patient the better as regards the operation. Mr. Mummery mentioned three cases in which the testicle had been gradually brought into its proper position by frequent gentle manipulation.

Mr. P. G. Lee (Cork) rather supported the view that syphilis predisposed to testicular disease. In Cork there was little or no syphilis but a great deal of tubercle and he saw no such affections of the testis.

Mr. Russell Howard said that of 78 cases of malignant disease of the testicle which was rare in children nearly all were sarcoma and 12 occurred in retained testes. Where only one testis was undescended he should remove it for fear of sarcoma.

Mr. E. M. Corner (London) considered that torsion of the testicle was now better recognised than formerly. The sign was pain recurring after exertion, especially where there was imperfect descent. He recommended orchidopexy and considered the prognosis better under seven years of age.

Mr. McAdam Eccles said that in 83 cases of malignant disease of the testicle collected at St. Bartholomew's Hospital only two occurred in undescended organs.

Mr. F. H. Brook (Swansea) and Mr. Russell Howard recorded cases of sarcoma of the tunica vaginalis.

The President of the section said that in cases of spinal caries there were often secondary affections of small joints and of glands but not of the testes. He was in favour of replacing imperfectly descended organs rather than of removing them.

Dr. Edington in a paper on

Some Abnormalities of the Penis

gave an anatomical account of 54 instances of various malformations of the penis met with in six years. There were 21 cases of hypospadias of the glans, six of the penis, and one of the perineum. There were four cases allied to hypospadias, ten of malformation of the raphe only, and 12 of torsion of the penis. Sketches of a number of these were appended.

Mr. Russell Howard explained that the great number of cases in which abnormality was confined to the glans depended on the fact that this part of the urethra was developed independently and later by extension backwards of the meatus to meet the penile urethra, which at first ended at the lower part of the corona.

Mr. H. Tyrrell Gray (London) gave an account of

Some Complications met with in Connexion with Meckel's Diverticulum.

All conditions, he said, were met with, from simple catarrh to actual gangrene. One of the cases represented primary diverticulitis with ulcer. Another presented 13 perforations in one diverticulum, while a third was attached to the superior abdominal wall by a blood cyst and presented two constrictions. The diverticulum was exposed to risk of torsion and injury, while deficient blood-supply rendered gangrene possible. Pain and swelling would be found usually below and to the right of the umbilicus, sometimes above, while the general symptoms resembled appendicitis. There were in his cases exacerbations of pain, vomiting, constipation, fulness in the recto-vesical pouch, swelling, and absence of respiratory movement below the umbilicus. Symptoms of intestinal obstruction occurred with history of previous attacks of abdominal pain. In one case excessive scarring at the umbilicus pointed to a congenital deficiency of the abdominal wall which was associated with the presence of a diverticulum. In another case there was marked retraction of the navel. Localised meteorism had been observed.

Mr. Brook cited a case which showed that inversion of a diverticulum might be the cause of intussusception.

Mr. C. A. R. Nitch (London) read a paper on

Cases of Pneumococcic Arthritis.

He said that in 1888 Weichselbaum showed that pneumococcic infection of joints and other parts might occur with or without lung implication. He cited two instances of

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8583 births and 3597 deaths were registered during the week ending August 3rd. The annual rate of mortality, which had been 12·3, 12·4, and 11·9 per 1000 in the three preceding weeks, further declined to 11·7 during the week under notice. During the first five weeks of the current quarter the death-rate in these towns averaged 12·2 per 1000, the rate in London during the same period being 11·9. The lowest death-rates in the 76 towns last week were 4·9 in York, 5·2 in Hornsey and in Reading, 6·7 in Tynemouth, and 6·8 in Burton-on-Trent; the highest rates were 15·8 in Oldham, 16·0 in Preston, 18·0 in St. Helens, and 19·4 in Sunderland. The 3597 deaths in the 76 towns last week showed a decline of 68 from the number in the previous week, and included 363 which were referred to the principal epidemic diseases, against 341, 397, and 398 in the three preceding weeks; of these, 113 resulted from measles, 88 from whooping-cough, 78 from diarrhœa, 36 from scarlet fever, 34 from diphtheria, and 16 from "fever" (principally enteric), but not one from small-pox. No death from any of these epidemic diseases was registered last week in Wolverhampton, Bury, Burnley, Huddersfield, Halifax, York, or in 13 other of the 76 towns; the annual rate from these diseases, however, ranged upwards to 2·3 in Sunderland and in St. Helens, 2·5 in Derby, 3·5 in Wigan, 4·4 in Cardiff, and 4·9 in Stockton-on-Tees. The fatal cases of measles, which had been 142 and 113 in the two preceding weeks, were again 113 last week, and caused death-rates ranging upwards to 1·2 in Walthamstow and in Blackburn, 1·7 in Derby, 2·0 in Stockton-on-Tees, 2·1 in Merthyr Tydfil, and 3·1 in Cardiff. The 88 deaths from whooping-cough were 37 below the number recorded in the preceding week; the highest death-rates from this disease were 1·1 in Oldham, 1·7 in St. Helens, and 2·0 in Stockton-on-Tees. The fatal cases of diarrhœa, which had increased from 39 to 73 in the three previous weeks, further rose to 78 last week, the highest death-rates being 1·0 in Birmingham and in Stockton-on-Tees, 1·1 in Walsall, and 1·8 in Wigan. Diphtheria caused a death-rate of 1·0 in Croydon. The mortality from scarlet fever or from "fever" showed no marked excess in any of the 76 large towns. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which in the 12 preceding weeks had risen from 2658 to 3586, had further increased to 3626 at the end of last week; 419 new cases were admitted during the week, against 493, 569, and 557 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 126 and 136 in the two preceding weeks, were 137 last week, and exceeded by 19 the corrected average number in the corresponding week of the five years 1902–06. The causes of 42, or 1·2 per cent., of the deaths registered in the 76 towns during last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Manchester, Salford, Oldham, Bradford, Hull, and in 49 other of the 76 towns; the highest proportions of uncertified deaths were recorded in Birmingham, Coventry, Liverpool, St. Helens, Rotherham, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 14·9 and 13·6 per 1000 in the two preceding weeks, further declined to 12·8 during the week ending August 3rd, but exceeded by 1·1 per 1000 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·0 in Leith and 11·2 in Edinburgh, to 13·9 in Greenock and 17·3 in Dundee. The 445 deaths in these towns showed a decline of 29 from the number in the preceding week, and included 60 which were referred to the principal epidemic diseases, against 60, 63, and 66 in the three previous weeks. These 60 deaths were equal to an annual rate of 1·7 per 1000, which exceeded by 0·4 per 1000 the mean rate during the same period from the principal epidemic diseases in the 76 large English towns; they included 21 which resulted from diarrhœa, 15 from "fever," 12 from whooping-cough, six from measles, four from diphtheria, two from scarlet fever, but not one from small-pox. The fatal cases of diarrhœa, which had been 19 and ten in the two preceding weeks, rose again to 21 last week, of which seven occurred in Glasgow, five in Dundee, and three in Edinburgh. The deaths referred to different forms of "fever," which had been 14 and 15 in the two preceding weeks, were again 15 last week, and included nine cases of cerebro-spinal meningitis in Glasgow, two in Leith, and one each in Edinburgh, Dundee, and Paisley. The fatal cases of whooping-cough, which had increased from 18 to 30 in the four preceding weeks, declined to 12 last week, of which eight occurred in Glasgow and two in Edinburgh. The six deaths referred to measles slightly exceeded the number in the previous week; four were recorded in Glasgow and two in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory organs, which had declined from 88 to 63 in the three preceding weeks, rose again to 68 last week, and were seven in excess of the number recorded in the corresponding week of last year. The causes of nine, or 2·0 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths did not exceed 1·2 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 21·5 and 21·2 per 1000 in the two preceding weeks, further declined to 18·0 in the week ending August 3rd. During the past five weeks of the current quarter the Dublin death-rate has averaged 20·1 per 1000, the rate during the same period being only 11·9 in London and 13·8 in Edinburgh. The 135 deaths of Dublin residents registered during the week under notice showed a decline of 24 from the number in the previous week, and included 16 which were referred to the principal epidemic diseases, against five and 12 in the two preceding weeks; of these, six resulted from measles, four from whooping-cough, three from diarrhœa, two from diphtheria, but not any from small-pox, from scarlet fever, or from "fever." These 15 deaths were equal to an annual rate of 2·0 per 1000, the death-rate during the same week from the principal epidemic diseases being 1·3 in London and 1·4 in Edinburgh. The six fatal cases of measles showed an increase of three upon the number recorded in the preceding week. The deaths referred to diphtheria, which had been four in each of the two preceding weeks, were again four last week. The two fatal cases of scarlet fever exceeded the number recorded in any week since April last. The 135 deaths from all causes in Dublin last week included 17 of infants under one year of age and 27 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were below those recorded in any preceding week of the current year. Five inquest cases and three deaths from violence were registered; and 57, or more than 42 per cent., of the deaths occurred in public institutions. The causes of five, or 3·7 per cent., of the deaths in Dublin last week were not certified; the percentage of uncertified deaths in London was 0·3 and in Edinburgh 4·1. The 115 deaths in Belfast included seven which were referred to cerebro-spinal fever.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned Surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet:—Edward Francis Power (dated Nov. 10th, 1904), Edwin Folliott (dated May 25th, 1905), George Ernest Macleod (dated Nov. 29th, 1905), and James Aquilon Forrest and Henry William Melvill Rees (dated Nov. 8th, 1906).

The following appointments are notified:—Staff Surgeon O. H. Rock to the *Hampshire*; Surgeons: L. M. Morris to the *Hampshire*; and L. C. Rowan-Robinson to the *Impregnable*. Civil Practitioner G. C. March Surgeon and Agent a Langton and Abbotsbury.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Majors are placed on retired pay (dated July 27th, 1907): George F. Alexander, John Paterson and Vesey H. W. Davoren. Major Arthur B. Hinde retire excessive amounts, or as the effect of a toxin acting like phosphorus. Probably the last was the true explanation and in cyclical vomiting the source of intoxication was probably the gastro-intestinal tract. The practical outcome was the importance of finding out whether acute acetonuria was present before an operation, for if this were so an anæsthetic would probably be disastrous. Wherever possible the acetone should be first eliminated by a course of alkalies. When acidosis was present, whether as a bout of cyclical vomiting or after an anæsthetic, every effort should be made to eliminate and dilute the poison by purgation and saline infusion and large doses of alkalies should be administered as an antidote.

The subject was briefly discussed by Professor W. D. HALLIBURTON (London), Dr. R. LEES, Dr. VOELCKER, Dr. G. A. SUTHERLAND (London), and Dr. CAUTLEY.

Dr. H. R. DEAN (London) read a paper on

The Classification and Diagnosis of the Varieties of Purpura Occurring in Children.

Excluding secondary or symptomatic cases the primary examples were divided into purpura simplex, purpura rheumatica, Henoch's purpura, and hemorrhagic purpura. Of 52 cases six occurred under the age of five years, 16 between five and ten years, 13 between 10 and 15 years, two between 15 and 20 years, and 15 over 20 years, 35 being under 15. The forms varied in degree rather than in kind, the simple form affecting only the skin, the rheumatic form involving some fever and pain in the limbs, and Henoch's purpura being associated with vomiting, diarrhœa, and abdominal pain, while the hæmorrhagic form was more general, affecting the mucous membranes and tissues.

Dr. H. I. PINCHES (London) read a paper on

Retro-pharyngeal Abscess

which occurred for the most part in the first year of life, and was not uncommonly associated with measles, scarlet fever, and diphtheria. Inflammation commenced in the tonsils and adenoid tissue, and spread to the peritonsillar or pharyngeal lymph spaces. So that peritonsillar abscess and retropharyngeal abscess were analogous. A purulent nasal discharge often indicated adenoids. There were 16 cases. The swelling was always to one side or the other, never truly central. Swallowing and breathing were embarrassed and the child was seriously ill, pale and sweating, and there was a peculiar muffled cry regarded as characteristic. The neck was rigid and the head kept motionless. The abscess usually projected on one side of the neck and there were enlarged glands. In the mouth, the pharyngeal and faucial mucous membrane was inflamed and the tongue furred. Diagnosis was made by touch rather than by sight. The prognosis was good if the abscess was opened early by the mouth, not externally.

Dr. T. N. KELYNACK (London) read a paper on

The Care of Tuberculous Children.

Deaths from tuberculous disease, he said, occurred largely between the ages of 15 and 35 years. Infection occurred in early life and from 2 to 6 per cent. of school children were affected. He urged greater care in prophylaxis in infancy and childhood as more effective in eradicating the disease than the attempts to cure the disease later in life.

THE ANNUAL EXHIBITION.

(*Continued from p. 340.*)

III.—FOODS AND FOOD PRODUCTS.

This section did not appear to be so well represented as on previous occasions. Beyond some special foods, as, for example, those enriched by the addition of protein and others in which the carbohydrates have been reduced or extracted for the use of sufferers from diabetes, there were, on the whole, but few novelties. The well-known firm of biscuit makers, Messrs. Peak, Frean, and Co., Limited, of Drummond-road, London, S.E., exhibited their comparatively new introductions, tilia biscuits, cocoa, and powder. Not long since we submitted these preparations to analysis, the results showing them to contain an important addition of milk protein. Their nutritive value is thus considerably increased. Tilia biscuits are packed in "damp-tight" tins. Messrs. J. Reynolds and Co., Limited (of the flour mills, Gloucester), exhibited excellent specimens of a specially prepared wheatmeal bread. The analysis shows a very satisfactory proportion of protein and phosphates, while the bran of the whole meal is ground exceedingly fine which renders it unirritating. The flavour is good and attractive. An interesting series of foods for invalids was shown by Messrs. Brand and Co., Limited, of 11, Little Stanhope-street, Mayfair, London, W. Amongst these should be mentioned a preparation of beef-tea which enables a really good beef-tea to be made in a few minutes; there were also shown some well-prepared jellies, including chicken, calf's foot, and turtle. Close by were the scientifically prepared milk foods of the Aylesbury Dairy Co. of St. Petersburgh-place, Bayswater, W. Here were koumis, humanised milks, milk sugar, and two foods known respectively as "humanoid" and "pollyta," the former being a concentrated preparation which on dilution resembles mother's milk, while the latter is a solid milk food suitable for infants after weaning. Messrs. Keen Robinson and Co., Limited, of Denmark-street, St. George in the East, London, E., exhibited their well-known patent barley which is prepared from grain of the best quality and is particularly suitable for making barley water. Virol is now well known as not only a concentrated food but as an easily assimilated one. It contains all classes of reparatives and is indicated particularly for infants suffering from malnutrition. A numerous assortment of specimens was shown by Messrs. Virol, Limited, of 152, Old-street, London, E.C. Messrs. Fairchild Brothers and Foster exhibited their well-known food products. Amongst these should be mentioned a lecithin preparation containing this peculiar organic phosphorous compound in solution. Its favourable effect on general nutrition is well recognised; the exhibit included panopeptone, which represents the nutritive value of beef and wheat flour in an easily assimilable state, and a number of preparations containing active pepsin. The Plasmon Food Products were well represented at the stall of International Plasmon, Limited, of 66A, Farringdon-street, London, E.C. Here were pure plasmon powder, biscuits, chocolate, cocoa, custard powder, and tea. Next to this stall were the foods of the Manhu Food Co., of 23, Mount Pleasant, London, W.C. These preparations are admitted to consist of a modified form of wheaten flour, the method, it is stated, rendering carbohydrates much more easily digested than when not so treated. An excellent series of starchless and sugarless foods, giving the practitioner an abundant choice of a diabetic food, was shown by Messrs. Callard and Co., of 74, Regent-street, London, W. These included bread, biscuit, jam, marmalade, jellies, chocolate, and so forth. "Virogen" is described as a compound of the protein of milk with the glycerophosphates of lime and iron. Specimens were shown by Virogen, Limited, of 115, Oxford-street, London, W., the exhibit including also diabetic bread and biscuits and virogen cocoa. The exhibit of Liebig's Extract of Meat Co., of 4, Lloyd's-avenue, London, E.C., attracted a good deal of attention. This company state that its concentrated foods are subject to strict analysis and scientific control at all the various stages of manufacture. The exhibit included the compound of meat extract and meat fibrin known as "Oxo" and the pure extract known as "Lemco." There were also specimens of corned beef, ox tongues, and oxtail soup. Messrs G. Van Abbott and Sons of Bardon-place, Crosby-row, Borough, London, S.E., exhibited their well-known foods which are suited to the special physiological requirements of sufferers from diabetes and obesity. The exhibits included gluten bread, almond bread, and other starchless and sugarless foods.

Medical visitors inspected this important department of the exhibition with obvious interest and in many instances evinced their curiosity so far as to accept the invitation to taste and to receive specimens for personal trial.

(*To be concluded.*)

UNIVERSITY OF CAMBRIDGE.—Mr. Adam Sedgwick, F.R.S., has been elected professor of zoology and comparative anatomy in place of the late Professor Newton. Mr. Sedgwick has been reader in morphology since 1882 and has recently resigned a tutorship of Trinity College.—The offer of the mastership of Downing College, vacated by the resignation of Dr. A. Hill, has been made to Professor Howard Marsh, professor of surgery in the University. It is understood that Professor Marsh has accepted the offer but the election cannot take place until October.—The third annual meeting of the Esperanto Congress will be held in Cambridge to-day (August 10th); a large gathering is expected.

spirit of criticism or of fault-finding that I write but simply because I am bewildered and perplexed by an attitude which seems to me to be opposed to all that I have learnt to admire in a great profession.

I am, Sirs, yours respectfully,

Huddersfield, July 30th, 1907. BENJAMIN BROADBENT.

EXPERIMENTS ON PROLONGED PROTEIN FEEDING.

To the Editors of THE LANCET.

SIRS,—The object of my letter in your issue of July 27th was to indicate to your readers that, since the conditions of Dr. Forsyth's experiments differed from mine in two fundamental particulars, a direct comparison of the results was out of the question. The letter published by Dr. Forsyth in THE LANCET of August 3rd prompts me to ask your permission to supplement the statements in my former letter by briefly summarising the present state of our knowledge of the influence of diet on the thyroid gland.

In the course of an experimental investigation into the nature of avian gout I incidentally observed that the administration of an exclusive meat diet to normal fowls induced a striking hypertrophy of the thyroid and parathyroid glands, with excess of colloid in the former gland. This observation appeared to indicate that diet modified the structure and function of the thyroid gland, a fact which had not, so far as I am aware, been previously ascertained. A repetition of the same experiments, using other animals, gave results which confirmed, and at the same time amplified, those previously obtained. Independent confirmation of my main conclusions has been furnished by Dr. A. Dingwall Fordyce in a paper published in the *British Medical Journal* and further evidence in the same direction was submitted by me to a recent meeting of the Physiological Society. Dr. Forsyth has shown in his recently published observations that an excessive protein dietary administered under conditions essentially different from those obtaining in my experiments induces a modification in the histological appearances of the pituitary gland, the change taking the form of excess of colloid, a point of much interest in the light of my earlier observations. The facts so far ascertained give promise that further investigations may yield results of much importance in human dietetics. In his letter Dr. Forsyth asks a question regarding the recognition of pathological appearances in the thyroid gland. This point will be dealt with more appropriately in a further communication on the subject which will shortly be published.

I am, Sirs, yours faithfully,

Edinburgh, August 4th, 1907. CHALMERS WATSON.

THE CORNEAL REFLEX IN ANÆSTHESIA.

To the Editors of THE LANCET.

SIRS,—My own experience of chloroform anæsthesia has led me to regard the corneal reflex as of little value as a guide to the measure of anæsthesia. The beginner always seems to attach special value to it, and if permitted worries at the cornea as though it were an electric bell-push until in self-defence (?) it refuses to respond. Apart from the mechanical injury which may be inflicted by the finger I have known corneal ulcers of extensive character produced by the chloroformist allowing his finger to become moistened with chloroform and then applying it all unconsciously to the patient's conjunctiva.

In teaching students I invariably warn them against over-estimation of the value of the corneal *reflex and urge them* to dispense with the use of it as far as possible. Surely with automatic respiration, muscular relaxation, *and* a contracted pupil we may be content to leave the cornea alone for the most part. Mr. Richard Gill well says "the contracted pupil is the measure of the lowest degree of anæsthesia" (and by this he means, I think, *workable surgical anæsthesia*). In some cases where one requires to induce a very *profound* anæsthesia I push the $CHCl_3$ until the pupil has lost its mobility, contracted down to around 2·5 millimetres, and begun to dilate again. With students I suggest *their* using a sluggishly mobile contracted pupil as their standard—that is to say, if the lids be closed for a moment and then sharply withdrawn the pupil *slowly* contracts, on the stimulus of light, say, from 3·5 millimetres to 2·5. Of course, with the pupil there are fallacies, and we cannot always rely on it. One morning I got a patient with the Argyll-Robertson phenomenon and next a patient with a pinhole morphia pupil. But I venture to think we can place more reliance generally on the pupil and its behaviour during chloroform anæsthesia than on the conjunctival or corneal reflex. To-day, for instance, I gave an old lady of 77 chloroform, and she was still phonating and certainly not in a state of surgical anæsthesia when the corneal reflex in both eyes had disappeared. And I believe my good friend Mr. H. Bellamy Gardner will admit I probably elicited it "*secundum artem*"!

I am, Sirs, yours faithfully,

Edinburgh, July 29th, 1907. THOMAS D. LUKE.

A PLEA FOR UNIFORMITY IN THE NOMENCLATURE OF ALKALOIDS AND THEIR DERIVATIVES.

To the Editors of THE LANCET.

SIRS,—Some years ago it was the custom in Britain to make all alkaloids and their derivatives end in *ine*, while glucosides, resins, and principles not alkaloidal were made to end in *in*. Now all is hopelessly mixed up, just as one finds in German literature. If the Germans send us over a new derivative of an old alkaloid editors, chemists, physiologists, and pharmacologists (not to speak of the poor despised clinician) seem to adhere to the ending which our Teuton friends give it. To take a few examples. In the same sentence I find eucaine and cocain (both alkaloids), and heroin and dionine, two morphine derivatives which came to us from Stockman and Dott, but which were neglected till an enterprising German firm took them up. The more or less pure ergot alkaloids are written cornutin-Keller, cornutine-Kobert, chrysotoxin, secalintoxin, sphacelotoxin, ergotoxine, hydroergotinin. I could go on multiplying examples but it is needless. It would be much simpler if investigators adhered to the old rule, so that when one came across a new preparation ending in *ine* we might conclude it was alkaloidal in nature.

I am, Sirs, yours faithfully,

Leeds, August 5th, 1907. GORDON SHARP.

HOW TO LEARN ESPERANTO.

To the Editors of THE LANCET.

SIRS,—Please allow me further space that I may answer inquiries which have reached me arising out of my letter in THE LANCET of August 3rd. Esperanto is, of course, best learned from a teacher, either orally or by correspondence. Ample particulars will be found in the current number of the *British Esperantist* (monthly 3*d.*). But anyone can easily teach himself. I would advise a beginner to get the *Whole of Esperanto for a Penny* and Grabowski's *Kondukanto* (2*s.*). The former will give him the grammar and vocabulary; the latter provides easy and most interesting reading. Having mastered these he should make Dr. Zamenhof his teacher. The *Ekzercaro* should be worked through, as given in Bullen's *Standard Course of Esperanto* (7*d.*). Then the *Fundamenta Krestomatio* (cloth 4*s.* 6*d.*) should be read and re-read; it is the classic and the ultimate court of appeal in Esperanto, besides being excellent reading. Lastly, Major-General Cox's *Grammar and Commentary* (2*s.* 9*d.*) will be found illuminative.

Every learner will find it well worth his while to pass the British Esperanto Association examinations. Conversation should be practised on every opportunity: a list of groups, with addresses, can be found in the *British Esperantist*. All the foregoing and other Esperanto publications, as well as further information, may be obtained from the secretary, British Esperanto Association, 13, Arundel-street, Strand, W.C.

I am, Sirs, yours faithfully,

W. WINSLOW HALL.

Kilburn, N.W., August 5th, 1907.

STATISTICS IN MEDICINE.

To the Editors of THE LANCET.

SIRS,—A considerable part of Dr. W. Hale White's admirable address, on which you commented at length last week, was devoted to demonstrating the inaccuracy that is too often displayed in the use of statistics, more especially when they are employed as special pleaders for a new cause. I on the subject of vivisection. It matters not at all that when a vote was taken at the end of the proceedings it was in favour of the abolition of vivisection. That is but little more than an incident, for the meeting was arranged by the secretary of the British Union for the Abolition of Vivisection, and it was to be expected that many supporters of the movement would be present.

Dr. W. R. HADWEN of Gloucester spoke against vivisection and Dr. T. EASTHAM of Hadfield opposed him. In a debate taking more than two hours it is clear that more arguments must have been employed than we have space even for mentioning, but it will be worth while to notice a few of the more important. Dr. HADWEN, inasmuch as he is a medical man, is less prone than some other antivivisectionists to make unfounded statements, but much of what he said did not rest on any firm foundation. For instance, he stated that little care is taken in experiments on animals to insure that the anæsthesia is complete, but he did not give any evidence of this so far as we may judge from the newspaper report. He also said that curare is frequently employed but Dr. EASTHAM showed that curare is very rarely used now, and even when it is employed some anæsthetic is usually administered as well. Dr. HADWEN also said that the operation of removal of the kidney was "quite common" in the time of HIPPOCRATES. We should be glad to learn what was the foundation for this statement. He also said that experiments on animals with drugs were useless because drugs have not the same effect on animals as on human beings. There is a small basis of truth for this assertion, for some drugs have unusual effects on some animals, but nearly all drugs have the same effect on nearly all animals as they have on man, and therefore with a little care we are fully justified in arguing from animals to man as to the effects of drugs. Dr. HADWEN was not in favour of the standardisation of pharmaceutical preparations, for he held that attempts to standardise by means of tests on animals must fail. He denied that experiments on the lower animals had anything to do with the discovery of the circulation of the blood and attributed this discovery to the microscope, although HARVEY'S work "Exercitatio Anatomica de Motu Cordis et Sanguinis" was published in 1628 and the first application of the microscope to the circulation was made by MALPIGHI in 1661. He also said that there was not a *single* infectious disease at the present day for which a specific microbe had been definitely proved to be the cause. He denied that antitoxin was of any use in diphtheria and he asserted that since the discovery of diphtheria antitoxin the mortality of diphtheria had increased; yet we know that the very aspect of the diphtheria wards of the fever hospitals has become changed and that the huge percentage mortality has enormously decreased. Appeals by Dr. EASTHAM to the opinion of the members of the Council of the Royal Society in favour of vivisection were rejected with scorn by Dr. HADWEN, for, said he, no medical man who dared to give vent to opinions against vivisection would ever be considered eminent. Finally, Dr. HADWEN said that even had experiments on animals resulted in proved success in aiding the alleviation or cure of human diseases, he would still look upon them as unjustifiable—what we dare not do to a human being we should not do to a dog. As already mentioned, the vote of the meeting was in favour of the total abolition of vivisection. We cannot but express our approval of the manner in which Dr. EASTHAM conducted the debate; he was well primed with facts and arguments and he did his best to put them in a form comprehensible to non-scientific minds. That he was defeated depended not so much on his facts and arguments as on the composition of the meeting.

In all antivivisection literature there are several important fallacies. It is generally taken for granted that cruelty and the infliction of pain are synonymous, and therefore it is argued that as vivisectionists do sometimes inflict pain they are necessarily cruel. But cruelty is the infliction of *unnecessary* pain or useless pain. To inflict pain is often far from cruel, sometimes even to the sufferer himself; but often it is advisable, or even necessary, to inflict pain, not so much for the benefit of the sufferer but for the benefit of others; and this is true of human beings and it is equally true of the lower animals. Dr. HADWEN in his opening speech at the debate ridiculed the idea that anæsthetics were largely employed in experiments, but the fact remains that in nearly every operation an efficient anæsthetic is used. A very large proportion of the "experiments on animals" consists of hypodermic and intravascular injections, and for these no anæsthetic is needed, and no anæsthetic is employed when similar injections are made in human beings. As we have said already, the greater part of the opposition to experiments on animals is due to misrepresentations of what is done in so-called vivisection. We honour the tenderness of heart of those who, hearing tales of horror, do their best to put an end to the possibility of such happenings, but those who mislead the ill-instructed and humane public incur a heavy responsibility indeed, for they are opposing the labours of men who work not so much for the advancement of science as for the benefit of the human race. With the increase of our knowledge of human pathology our knowledge of the pathology of the lower animals increases also, and thus, though men benefit at first from experiments on animals, the benefit is not restricted to us but extends also to the animal world.

The Supply and Rate of Remuneration of Midwives.

THE problem as to whether the Midwives Act is to work successfully or not is one which only the future can decide with certainty. At the same time there are many questions concerned with the present and future working of the Act which are of the utmost importance to all interested in this matter. The Association for Promoting the Training and Supply of Midwives recently appointed a committee to collect information on the question of the supply and remuneration of midwives and this committee presented a very valuable report which contains a large amount of information on these and allied questions. We published the document in full in THE LANCET.[1]

The supply of fully trained midwives must be determined by the demand for their *services* and the possibility of the women who take up this work being enabled to women at the Western Infirmary in room of Dr. W. L. Reid who has retired from that position.

---

[1] THE LANCET, July 20th, p. 178.

Graduation Ceremony at Glasgow University.

The summer graduation in medicine took place last week when the degree M.B., Ch.B., was conferred by Principal MacAlister on 95 graduates, four receiving the degree with honours and 13 with commendation. At the close of the ceremony the Principal conveyed the congratulations of the Faculty of Medicine to Sir Thomas McCall Anderson on his appointment as physician-in-ordinary to the King in Scotland in the place of the late Sir William T. Gairdner. Thereafter Professor Noel Paton delivered a short address to the graduates. He remarked at the outset that he did not think their success as students was to be estimated so much by the amount of information they had acquired as by the extent to which their love of knowledge had been developed. To his mind the least desirable of the medical profession was the so-called "practical man" who, through want of intelligence and imagination, was unable to see the depth of his ignorance and who was not content merely himself to go on without adding to the sum of knowledge but who was ready to jibe and to jeer at those who gave their lives to attempts, however unsuccessful, to pierce the cloud of their ignorance. He hoped that the Carnegie trustees would be able to arrange for a stipend being paid to their fellows somewhat more liberal than at present. It was impossible to expect men to devote themselves to science on a less income than they could make as assistants in practice. Until a few years ago those who elected to prosecute research had to resort to the laboratories of Germany and France, but now the laboratories of this country rivalled the laboratories of Germany, and in every university town the young graduate found at his door every facility for the prosecution of research. Especially at Glasgow were such facilities afforded, for at the present time no university could boast the possession of finer laboratories devoted to medical science. Let them hope that the work that came from their laboratories and their school in the future would justify the efforts of their late Principal and his colleagues, who were not afraid to be in advance of the immediate requirements of the university, and who saw how she must be equipped if she was to take her due place in the advance of medical science. Time given to research work he assured them was not lost to the practical man. The conditions of the scholarships for this work might at present be too exacting, but it was to be hoped that before the next quinquennial distribution of the funds some more elastic arrangement would be made by which the scholar would not be required to give his whole time to laboratory work but would be allowed to widen his professional education.

Death of Dr. John Pirie.

The intimation of the death of Dr. John Pirie will be received with regret by members of the medical profession in the West of Scotland. Some years ago Dr. Pirie retired from practice in Glasgow, and about a year ago went to reside at Campbeltown, where he passed away last week in his eighty-first year. He was a native of Ross-shire and was educated at the University of Aberdeen, taking first the degree of M.A., and in 1846 that of M.B. About the year 1852, after graduating M.D., he went to Campbeltown, where he remained till 1867, when he came to Glasgow, where the rest of his active life was spent. Dr. Pirie was a fine representative of the physician of the old school, genial, kindly, and generous, with a rich fund of wit and humour. By his professional brethren he was held in the highest respect. From the time he settled in Glasgow he took a great interest in the necessitous poor and was one of the founders of the Glasgow Medical Mission. Dr. Pirie was married to a daughter of Dr. Harvey, a well-known surgeon in Campbeltown, by whom he was predeceased.

Enteric Fever in Peterhead.

During the past week 43 cases of enteric fever have been notified in Peterhead. The total number of cases notified since the fever broke out is 293, of which 98 have been treated in the hospital and the remainder at home. 36 patients have been discharged and two have died during the past week. Out of the total number of cases 120 have fully recovered.

Dundee Lunacy Board and Alcoholism.

At a meeting of the Dundee lunacy board last week the medical superintendent said he had found that alcoholism and heredity were the chief factors inducing insanity amongst the patients at the asylum. What, in his opinion, aggravated the temptation to drink was the public sanction, both by the multitude of licensed houses and the slackness of public opinion.

The Carnegie Trust: Awards for Research to Aberdeen Students.

The following awards for research have been made to Aberdeen students:—Fellowship: Hugh MacLean, M.D. Aberd., the Carbohydrate Material and Ferments of Blood. Scholarships: Williamina Abel, M.B., Ch.B. Aberd., the Development of the Peripheral Nervous Mechanism of the Alimentary Canal in Vertebrates. Walter J. Dilling, M.B., Ch.B. Aberd., the Influence of Changes in the Reaction of the Blood on the Muscular Tone of the Vascular System. Grant: Alexander Low, M.A., M.B., C.M., lecturer in embryology, University of Aberdeen, Embryological Research, more Especially the Reconstruction of Original Embryological Models.

August 6th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Use of Tuberculin as a Means of Diagnosis.

FOR diagnosing tuberculosis M. Paul Claisse makes use of repeated small injections of tuberculin, a procedure described by M. Moeller, M. Loewenstein, and M. Ostrowsky at the Tuberculosis Congress in 1905. This method depends on the fact that if a healthy adult is injected with 0·2 milligramme of tuberculin every three days reaction only commences with the seventh injection, but if the person is tuberculous this reaction, which includes pyrexia, auscultatory symptoms, and a special form of malaise, may make its appearance at the first, second, third, or fourth injections. There is therefore between the fourth and seventh injections an interval which serves to distinguish a non-tuberculous person from a tuberculous one. This method is quite harmless and has yielded M. Claisse very distinct results, enabling him to solve some puzzling clinical problems. It is contra-indicated when pyrexia is present, because the necessary inferences cannot then be drawn from the temperature curve. Its use ought to be restricted to the examination of latent or masked cases of tuberculosis. A positive reaction enables tuberculosis to be diagnosed at an early stage before the appearance of clinical symptoms. M. Claisse read a paper on this subject at a recent meeting of the Société Médicale des Hôpitaux.

The Hôpital Beaujon.

Reference has already been made in this column to the fact that several of the Paris hospitals are in need of reconstruction, either on account of the unsatisfactory condition of their structure or because the continual extension of the city has had the effect of making their position too central. The Hôpital Beaujon not only suffers from both these disadvantages but is, moreover, in the midst of one of the most fashionable quarters of Paris, so that the sale of its site will easily provide a sum more than sufficient for the erection and furnishing of a new hospital. A site has been selected between the Porte de Villiers, the Porte des Ternes, the Route de la Révolte, and the Boulevard de Villiers, and it is intended to begin work there very shortly.

The Swallowing of Foreign Bodies by Insane Persons.

At a meeting of the Société Médicale des Hôpitaux held on July 5th M. Marie described three cases in which foreign bodies were swallowed by insane persons. In one of them the objects swallowed were metallic, consisting of iron, copper, tin, steel, or silver. Radiographs were shown that had been taken from a woman who had died from phlegmonous disease of the ileum after swallowing more than 100 needles; specimens in which needles were imbedded in bone were also exhibited. An insane man had swallowed 30 small stones, four silver five-franc pieces, and a large number of objects which were passed by the anus after more than 15 days. A third patient swallowed metallic articles, small stones, and fragments of glass and earthenware. He died from peritonitis and at the necropsy more than 50 foreign bodies were found in the small intestine.

The Treatment of Nail Biting.

At a meeting of the Academy of Medicine held on useful in disease. Hardly any of our readers will dissent from this view or will grudge to the temperance party the credit of having taught the medical profession valuable lessons in the use of alcohol. But the drunkard and the right user of alcohol must be kept separate in the minds of all who desire to think accurately.

In the section of State Medicine a paper was read by Mr. H. H. TIDSWELL of Torquay on "The Influence of the Tobacco Habit on the Health of the Individual and the Nation," and formed a striking instance of the loose and unscientific statements which are deplored by medical men. Mr. TIDSWELL's address was a good example of the unbalanced fervour of a convert. He was once a moderate smoker—at least, he says so—but if the amount that he was wont to smoke happened to be more than was good for him he was not moderate at all, however scanty his daily consumption of tobacco was. At any rate, he is now an immoderate non-smoker, and his arguments are illogical and unsound. He states that tobacco contains a deadly poison, nicotine, and further that no vital part of the body escapes the poisonous action of nicotine. He implied that therefore the smoking of tobacco meant the absorption of this deadly poison. In so doing he placed himself on one or other horn of a dilemma. Either he did not know that in tobacco smoke there is next to no nicotine or else knowing this fact he suppressed it. Let us quote two other inaccurate statements which he made. "The only use of tobacco was to keep off mosquitoes and as there were no mosquitoes in this country they had no excuse for smoking tobacco." Now tobacco smoke in respirable quantity does not keep off mosquitoes and there are plenty of these insects in our country. "Smoking was a national danger ...... boys were killing themselves by hundreds and thousands." Smoking is very bad for boys, but why try to impress this fact by manifestly absurd exaggeration? The evil effects of such loose statements are not apparent when they are made. An audience of medical men will as a whole appraise such a paper at its proper value. But a certain section of the lay press, quick to seize upon any sensational statement, publishes with apt headlines remarks of the kind we have quoted, and the mass of the population are gulled thereby. We yield to no one in the opinion that smoking is bad for children but so also are many other things which can be usefully and safely enjoyed by an adult.

Alcohol and tobacco, or perhaps we should say alcoholic beverages and some form of drug analogous to tobacco, have been in use by mankind, both civilised and savage, since the dawn of history. Their use and their abuse have been reckoned upon for countless ages, though we have lately grown much wiser in these matters with the increase of our physiological knowledge and our far greater opportunities of drawing statistical conclusions of international or universal import. But our reasoning powers have grown also and we are not to be terrified by bogey stories. The lines upon which temperance reform should go must be temperate. A powerful personality like MAHOMET or Father MATHEW may persuade his converts for a time when swayed by other motives, such as the religious motive, to give up alcoholic drinks. But directly the enthusiasm wanes the asceticism lessens. True temperance can only be inculcated by accuracy of statement, by example, by precept, and by the preaching in season of the fact that the body is a priceless possession which every man holds in trust not for himself alone but for his fellows. Already it is recognised by law that a man whose body is affected with certain diseases is a danger to his fellows, and if he or his friends do not comply with certain regulations they are punished. Even now people are fined for being drunk and disorderly. We should like to see a penalty extended to those who are drunk without being disorderly. If it could be impressed upon people that they have no right to poison their bodies with any drug whatsoever the evils rightly complained of by temperance lecturers, but no less deplored by those of us who make a right use of alcohol and tobacco, would cease. But loose and inaccurate statements such as we have referred to above are a very fountain of harm.

Annotations.

"Ne quid nimis."

THE MULKOVAL DISASTER.

A NECESSARY tribute was paid last week by Mr. Morley to the value of the Haffkine prophylactic against plague; and this fact makes it to our mind perfectly extraordinary that the Secretary of State for India, who stands so high amongst our statesmen as a brave and fair man and a logical thinker, does not take steps to do Mr. Haffkine justice in the matter of the Mulkoval disaster. Mr. Morley has so far declined any action on the ground that reports have been received by the Government from impartial and independent sources which make further consideration of the matter unnecessary. But it is impossible that this attitude should be maintained. On July 29th a letter was published in the *Times*, signed by Professor Flexner, Professor Ronald Ross, Professor R. T. Hewlett, Professor A. S. Grünbaum, Professor W. J. Simpson, Professor R. F. C. Leith, Professor W. R. Smith, Professor G. Sims Woodhead, Professor E. Klein, and Professor Hunter Stewart, in which the signatories expressly state the view already put forward very clearly by ourselves[1] that the case against Mr. Haffkine's laboratory collapses upon investigation. All those who signed that letter are scientific men, experts occupying responsible positions as pathologists or workers in the domains of public health. Thousands of bacteriologists throughout the world have been educated on Professor Klein's and Professor Hewlett's scientific publications, treatises, and text-books. Professor Klein has now for over 20 years acted as bacteriologist to the Local Government Board while conducting this department of study at St. Bartholomew's Hospital Medical School. Professor Sims Woodhead, professor of bacteriology in the University of Cambridge, is among our leaders in serotherapy, and Professor Flexner of the Rockefeller Institute in New York is one of the chief representatives of bacteriological and pathological knowledge throughout the world. Professor Ronald Ross's work and position are, of course, known of all men; and if we do not enumerate the claims of the other signatories upon immediate attention it is only because they are generally recognised as leaders of scientific thought and perfectly vouched for by the importance of the universities which have sought their collaboration. But the signatures of well-informed people do not necessarily to scientific research and in the second place it prepares sera against certain diseases, which sera can be obtained by medical institutions and practitioners. Although there are many horses bought every few months only those are selected which, after certain experiments, prove to be sufficiently strong and have a considerable power of forming new blood. Artillery horses are preferred because of their endurance. The age of the animals must not be less than six years. They are very well kept and special care is taken to insure the cleanliness of the stalls. In the stables there are five horses which have been yielding serum for upwards of ten years, the record having been reached by an animal which lived 25 years in this capacity. At present there are 26 horses immunised against diphtheria, two against scarlet fever (by Dr. Moser's system), three each against cholera, dysentery, typhoid fever, and tetanus, two each against streptococcal infection and puerperal fever, and one each against pneumococcal and meningococcal infection. Some of the horses, like the one which is immunised against tetanus, produce a peculiar kind of serum which is very strong, stronger than most other horses can produce. The animals are brought out into the fresh air daily for two hours, and those which were formerly saddle horses are ridden regularly so as to keep them in good condition. About 12 per cent. of them are pronounced unsuitable for the institute every year either on account of the inferiority of the serum obtained from them or because they do not overcome the inoculated disease. Horses with a very thin fine skin are the best for the required purpose. As regards the quantity of the serum prepared in the institute 71,506 bottles of anti-diphtheritic serum were made and sold in 1905 and 75,000 bottles in 1906, together with 7500 doses of anti-scarlatinal serum and 2000 doses of dysentery serum. Since 1906 the institute has been self-supporting, as the sale of the sera to private patients covers the cost of manufacture. The quantity of blood taken from each animal amounts to six litres (11 pints) each time, and as this is repeated ten times a year 110 pints of blood have to be reproduced by the organism within a year.

---

[1] THE LANCET, Feb. 2nd, 1907, p. 299, et seq.

The Increase of Hospital Accommodation within the last 30 years.

An interesting comparative study of the accommodation provided by the State for the treatment of disease has just been published and shows that such accommodation for patients of the poorer class has been greatly extended during the last 30 years. In 1877 there were in Austria, with a population of 20,500,000, altogether 161 hospitals which contained 18,960 beds, or about one bed per 1300 of the population. Within 30 years (i.e., up to 1907) the population has increased to 27,000,000 and the hospitals at present number 254, but the number of beds has been nearly doubled, there being now a total of 37,610 beds—i.e., one bed for about 800 of the population. This ratio is naturally different in the different countries of the empire, as the industrial, densely populated districts are better provided for in this respect than the purely rural parts. There is also clearly visible a tendency to diminish administrative expenses by centralising the charitable institutions, so that only large hospitals are built now. The costs of administration were formerly from 25 to 30 per cent. of the total expenditure of all the hospitals, whilst now this item stands at only from 15 to 20 per cent. This is the more remarkable if it is compared with the fact that 30 years ago each patient cost the State about 1*s*., whilst now he costs 1*s*. 6*d*. The lunatic asylums were then 21 in number, with only 5580 beds. Now there are 36 asylums with 16,400 beds and another one which is in course of construction will accommodate 3000 inmates. The alarming increase of mental disease, which has already led to the appointment of a special committee to investigate the cause of this increase, is thus illustrated only too vividly. The number of lying-in and maternity wards has not been increased during the time taken into consideration, but the old institutions have been enlarged, so that at present they contain 2071 beds, as compared with 1529 beds in the year 1877; about 25,000 children are born yearly in these establishments.

The New Hygienic Institute.

One of the four large university institutes to be erected within three years has been now completed and will be made ready for use within a short time. This, which is the Institute for Hygiene, is a magnificent four-storey building, situated a few minutes' walk from the General Hospital. It has three frontages to streets and another side overlooks a large garden. It will contain Professor Schattenfroh's class-rooms of hygiene, the institute of Professor Paltauf for serum treatment, the pathologico-historic museum, the laboratory for examination of food, and two large lecture rooms, each with seats for 250 students. Convenient housing accommodation for the animals to be used in experiments and ample disinfecting apparatus are also provided, so that all kinds of scientific research as well as practical work can be carried on. The cost of the building is comparatively low, the outlay on construction being £80,000 without the scientific outfit. The neurological and the embryological institutes will be commenced very soon, so that within three years there will be schools provided with all modern facilities, where students will find ample opportunity for earnest work.

The Treatment of Snake-bite.

In a communication published in the *Wiener Klinische Wochenschrift* Professor Riehl points out that during the last few years poisonous serpents have been constantly increasing in number in the southern parts of the Austrian empire. There are chiefly three kinds of these serpents found here and they all belong to the species vipera The rewards offered by the Government for the destruction of them have not been very efficient, although more than 6000 have been killed in one year in the small district of Styria. The mortality of persons bitten by serpents in Europe has been given as between 10 and 25 per cent. The best treatment must aim at destroying the poison at the part bitten and at preventing its absorption into the system. Several methods, such as cauterisation, bleeding, compression, and the application of a ligature, have been advised for these purposes. Professor Calmette's antitoxin against cobra and rattlesnake poison has the disadvantage of being specific for these poisons only, so that it is inapplicable in Austria. Extensive trials have now been made by Professor Calmette and Professor Paltauf of methods to prevent poisoning by treating the affected part with a solution of chlorate of calcium. A solution of one part of this substance in 12 parts of water is to be diluted before use with six times as much water and from ten to 12 cubic centimetres are to be injected by means of a Pravaz syringe around the bite so that the poison may be neutralised. This simple method is said to be efficacious for all sorts of snake-poison. The earlier treatment is instituted the better the result. Professor Riehl has had small packets put up by the pharmaceutical druggists, containing a Pravaz syringe, two sterilised injection needles, a small quantity of the solution, and a small mixture glass with instructions for using the whole packet. It is sometimes more handy to use not the solutions but the solid chlorate of lime in pastilles. Such pastilles are now to be had in the hotels and hunting lodges in the districts where snakes abound and in small villages the mayor may keep them, so that serious accidents are not so likely to occur now as they were formerly.

August 5th.

Obituary.

SYDNEY RUPERT HODGE, M.R.C.S. ENG., L.R.C.P. LOND.

THE death is announced, by cable, of the Rev. Sydney Rupert Hodge, senior medical officer of the Wesleyan Mission Hospital, Hankow, China, which took place suddenly on July 21st, at Kuling, near Hankow, where he had gone for a holiday. Mr. Hodge was the son of the late Sydney Bryan Hodge of Highbury-grove, London. He was born in 1859 and received his education at the Leys School, Cambridge. He entered Richmond College as a candidate for the Wesleyan ministry, but later decided to become a medical missionary. For this purpose he studied at the London Hospital and eventually qualified in 1886 as M.R.C.S. Eng., L.R.C.P. Lond. In the same year he was sent out to China to take medical charge of the Wuchang District, he being stationed at Hankow. Through his instrumentality and untiring energy the Hankow Mission Hospital (which had fallen into ruins) was rebuilt, but until the buildings were ready Mr. Hodge saw patients and even performed operations in his study. At Hankow he laboured for 20 years with conspicuous success. Unsparing of his own energies he has literally spent his life in the service say, they class diseases as nearly as possible according to anatomical location rather than according to their nature. Dr. Farr was the superintendent of the statistical department in the General Register Office, London, from 1838 to 1880, and was succeeded by Dr. William Ogle, who in 1886 adopted a new classification. The nosological system of the International Institute of Statistics, or the Bertillon system, as it is usually called, differs considerably from the Ogle-Farr index and includes two classifications—one for the compilation of statistics of morbidity and the other for causes of death. It has the advantages of wide recognition and practical convenience, and in these respects Mr. Knibbs believes it to be so much superior to the Farr-Ogle nosological index used in Australia that he recommended its adoption at the Australian Conference of Statisticians which met in November and December last. After some discussion that recommendation was accepted. No classification, however, is perfect all round, and Mr. Knibbs points out that the ascription of a death to a single definite cause is essentially empirical. This is probably inevitable, but it is nevertheless undesirable that the classification of causes of death should be governed by any etiological view which, from its nature, would be liable to vary from one country to another or with the prevalence of particular opinions. For instance, cirrhosis of the liver may be a consequence of alcoholism. Alcoholic impairment of the whole system may perhaps be followed by a fatal attack of nephritis. The Bertillon classification proposes that where the first disease is fully indicated it shall be recorded under "cirrhosis of the liver" and the second disease under "Bright's disease." According to this classification neither of these cases is to be recorded under alcoholism, so that the method has distinct limitations from the point of view of one who wishes to study the consequences of over-indulgence in alcohol. From one standpoint it might be desirable to know what statistical evidence there was of the number of deaths attributable directly and indirectly to a specific cause, but this would involve the impossible condition that the whole record of deaths should be examined and tabulated for each of such causes.

HIGH INFANT MORTALITY AT STALYBRIDGE AND PRESTON.

IN his annual report for 1906 Mr. F. Vacher, the medical officer of the county, says that Stalybridge has a bad record and the highest *infantile mortality* in Cheshire—206 per 1000. Preston, however, shows that in Lancashire places may be found that closely rival Stalybridge in its bad pre-eminence. During 1906, 200 children per 1000 died, as compared with 150 in 1905, the excess being due to an epidemic of measles in the former year which accounted for 122 deaths, an increase of 50 per cent. on the previous year. There were also 219 deaths from diarrhœa, an increase of 100 per cent. It is interesting to learn that in the *opinion* of Dr. R. C. Brown, the consulting medical officer of health of Preston, the cause is one that ought to have led to opposite results. "Good trade," said Dr. Brown, "had been the main cause of the increased infantile mortality." Many mothers who had not worked in the mills for years had, during the good trade of the last eighteen months, owing to the demand for labour, gone back to the mills, so that the care and attention which the children should have had were to some extent wanting. Another cause dependent in great part on the increase of mill work was artificial feeding. "Ten per cent. only of the deaths from *diarrhœa* were of children who were breast fed." It may be remembered that some little time ago attention was drawn to Mr. A. W. Martin's (of Gorton) picture of a race of flat-chested, breastless women as the mothers of the children on whom the continuity of our race depends. Dr. Brown *mentioned as a fact that out of every four married* women who went to the mill three had no need to go for pecuniary reasons. One of the Preston councillors looked on the matter from a different standpoint. He mentioned a recent day when the temperature was 90° F. and when what he called "live steam" was being blown into one weaving-shed in the town, saying that mothers could not be healthy under such conditions Still, all this, bad as it is, only adds other factors to those given by Dr. Brown. So, too, the early marriages at the age of 16 or 17 years, which according to the statement of another councillor are common among these boys and girls before they themselves are properly developed, all tend to show that Preston is not to be looked upon as the chosen cradle of an imperial race *Apropos* of the above, on the same day as the meeting of the Preston council, the annual meeting of the local branch of the National Society for the Prevention of Cruelty to Children was held, and the report showed that out of 277 cases investigated, 273, involving the welfare of 674 children, were found to be true. The report went on to say that when it is borne in mind that the children are compelled to live in dirty homes, are fed constantly on improper food, and are the victims of parental laziness or indifference, "the wonder is not that Preston's death-rate stands at the figure it does but that it is not considerably higher." Much might be done to teach girls in the elementary schools plain lessons on cleanliness and the food suitable for infants, but more attention seems to be paid to other matters that are of less moment than the health of the coming generation. It is not encouraging to see that a well-known educational expert is reported as saying that to advise the working woman as to the care of her children is to insult her, when the ignorance of a large proportion of the working women of the country after more than 30 years of "compulsory education" is more than dense.

THE WORK OF THE LIVERPOOL COUNTRY HOSPITAL IN THE CURATIVE AND EDUCATIONAL TREATMENT OF CRIPPLED CHILDREN.

OUR attention has been drawn to a correspondence recently published in the *Liverpool Courier* by Colonel Robert Montgomery, the chairman of the Liverpool Country Hospital for Children, between the Lord Mayor of London and himself with reference to the terms of Sir William Treloar's appeal on behalf of his fund for the systematic relief and treatment of crippled children. In the opening paragraph of that appeal the statement is made that though there have been special institutions in other countries for the treatment of crippled children suffering from chronic diseases, no such institution exists in England. Colonel Montgomery informed the Lord Mayor that such an institution has existed in the hospital at Heswell, over which he presides, for the last ten years, and forwarded to his lordship a full account of its work. In reply Sir William Treloar repeated the assertion that so far as he was informed "there is in this country no institution dealing in a systematic way with the disease of tuberculosis of the bones in children at an early age and giving them at once curative and educational treatment." The chairman and the honorary medical staff sent another letter stating in the fullest manner the work that the Liverpool Country Hospital is doing and pointing out that not only are its aims identical with those of the Lord Mayor's fund but that the methods adopted are a matter of general knowledge amongst those interested in the study of disease in children. From the correspondence, as we have seen it, we consider that Liverpool has well proved her claim to be the pioneer city to provide against a sadly urgent need, and we regret that in his reply

Douglas, Greenock; Isaac Flack, Galway; Henry Frank Collins, Edinburgh; Alexander Baxendale, Bolton; and Robert M'Connell Blair, Crookston.

Final Examination (and admitted Licentiates of the Coöperating Bodies).—John David Jones, Llanygraion, North Wales; James Finbair Jefferies, Cork; John Robert Dunn *Holtby* (with honours), Belfast; Hugh Clement de Souza, Rangoon; Walter Riddell, Glasgow; Isaac Flack, Galway; George Ernest Nash, Hove, Sussex; Walter Ernest Barrett, Leeds; Gilbert Elliot Aitken, Edinburgh; Robert Kay Nisbet, Glasgow; David Williamson Morison, Canada; Cuverji Ruttonji Veval, Bombay; Jitendra Nath Rai, Punjab; Clare Annis Langmaid, Canada; Bhairawnath Donanath Khote, Bombay; Edwin George Hodgson, Canada; and *Charles Jacobs* Tillekeratne, Ceylon.

VICTORIA UNIVERSITY OF MANCHESTER.—At *examinations* held in the Faculty of Medicine in July the following candidates *were successful* in the subjects indicated:—

FIRST M.B. AND CH.B. EXAMINATION.

Materia Medica and Pharmacy.—L. T. Challenor, L. W. Howlett, Newton Matthews, Jane C. Miller, Lovell Moss, R. P. Stewart, William Stirling, J. S. B. Stopford, G. K. Thompson, William Warburton, and Charlotte E. Warner.

SECOND M.B. AND CH.B. EXAMINATION.

Anatomy and Physiology.—Estelle I. E. Atkinson, G. M. Benton, C. G. Brentnall, S. J. Clegg, J. F. Cocker, G. T. Cregan, H. A. Dunkerley, Gertrude H. Geiler (Anatomy), S. A. Winstanley, and F. G. Wrigley.

Materia Medica and Pharmacy.—A. E. Ainscow, Rupert Briercliffe, John Cowan, V. S. Cox, E. R. Eatock, C. W. Fort, P. S. Green, Edgar Grey, Harold Harrison, Harold Heathcote, R. C. Hutchinson, R. B. Jackson, Geoffrey Lapage, James Leach, J. D. Mercer, W. Hoyle Parkinson, Alexander Porter, J. B. Scott, W. A. Sneath, J. P. Stallard, James Walker, and H. C. Wright.

THIRD M.B. AND CH.B. EXAMINATION.

R. J. Batty.

Hygiene.—J. A. Bateman, T. B. Bolton, W. C. Denniston, Frances M. Huxley, E. K. Lomas, W. P. Marshall, John Morley, M. C. Skillern-Lawrence, John Thompson, R. B. Thompson, B. W. E. Trevor-Roper, W. W. Uttley, T. G. Williams, and A. E. Woodall.

FINAL M.B. AND CH.B. EXAMINATION.

Part I.—Norman Booth, C. H. Broomhead, Elsie Brown, George Crawshaw, J. H. C. Green, and Ernest Howe.

Part II.—J. W. Bride, G. W. Bury, Harold Coppock, D. J. Dakeyne, J. F. Dow, † J. A. Fairer, Frederick Hall, † Frank Hartley, † Robert Lakin, V. D. Madgavkar, Peter Moran, Wilfrid Nightingale, Alice Oberdorfer, George Rainford, Robert Robertson, Douglas Rodger, Elsie M. Royle, Vincent Southwell, *T. W. Todd, G. B. Warburton, Henry Whitehead, and N. R. Williamson.

* With first-class honours. † With second-class honours.

CH.M. EXAMINATION.

A. R. Thompson.

DIPLOMA IN DENTISTRY.

Final Examination.—J. L. Reynolds and Albert Torkington.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berne:* Dr. Osterle has been appointed Extraordinary Professor of Forensic and Pharmaceutical Chemistry.—*Düsseldorf:* The New Medical Institutes, which have just been erected at a cost of £325,000 for the Academy of Practical Medicine, were publicly opened by the Prussian Minister of Education on July 27th.—*Giessen:* Dr. H. Köppe, *privat-docent* of Children's Diseases, has been promoted to an Extraordinary Professorship.—*Jena:* Dr. Wilhelm Lubosch, *privat-docent* of Anatomy, has been promoted to an Extraordinary Professorship.—*Leipsic:* Dr. Paul Schmidt has been recognised as *privat-docent* of Hygiene.—*Lyons:* Dr. Collet, *agrégé*, has been appointed to the chair of General Pathology in place of Professor Mayet. Dr. Pic, *agrégé*, has been appointed to the chair of Therapeutics in place of Professor Soulier. Dr. Roque, *agrégé*, has been appointed to the chair of Internal Pathology in place of Professor Teissier.—*Munich:* Dr. W. Brasch has been recognised as *privat-docent* of Nervous Diseases.—*New York (College of Physicians and Surgeons):* Dr. Baruch has been appointed Professor of Hydro therapeutics.—*Paris:* Dr. Nicolas of Nancy has been appointed to the chair of Anatomy in place of the late Professor Poirier. Dr. G. Ballet, *agrégé*, has been appointed to the chair of the History of Medicine and Surgery in place of Professor Déjerine.—*Toulouse:* Dr. Audebert, *agrégé*, has been appointed to the chair of Clinical Midwifery.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.—The usual monthly meeting of the executive committee of this society was held at 6, Catherine-street, Strand, London, W.C., on July 26th. The chair was taken by Mr. J. Brindley James and there were also present Dr. St. Clair B. Shadwell, Dr. F. S. Palmer, Dr. M. G. Biggs, Mr. F. S. Edwards, Mr. J. F. Colyer, Dr. F. J. Allan, Dr. J. W. Hunt, Mr. Edward Bartlett, and Dr. J. B. Ball. The records of the society for the first half of the year are very satisfactory. As the number of the members standing grows the amount of sick pay disbursed naturally increases, but this was expected and fully provided for when the table of rules of contribution were settled, and the reserves of the society have grown until they now amount to over £200,000. Over two dozen of the members are now drawing the annuity—usually £104 9*s.*—provided for those who are permanently incapacitated from professional work. Prospectuses and all further information may be obtained from the secretary, Mr. F. Addiscott, 33, Chancery-lane, London, W.C.

PRESENTATION TO A MEDICAL PRACTITIONER.—On July 26th Dr. T. Outterson Wood was presented with a silver bowl by members of the committee of management and the medical staff of the West End Hospital for Nervous Diseases, Welbeck-street, London, W., upon his retiring from the post of senior physician, which he had held for so many years, and his being appointed consulting physician to the hospital.

DONATIONS AND BEQUESTS.—By the will of Mrs. Maud Hand of Burton House, Stafford, £10,000 have been left in trust for the purchase of a site and the erection and endowment of a convalescent home for five or more children of the county of Stafford in memory of her son, and £1000 to the Great Ormond-street Hospital for Children for a "Kenelm Cot Bed."—Under the will of Mrs. Martha Miller of Fitzjohn's-avenue, South Hampstead, N.W., £1000 have been left to the Earlswood Asylum for Idiots, £1000 to the London Orphan Asylum, Watford, and £1000 to the West Sussex, East Hants, and Chichester Infirmary.—Miss B. Osborn of Brown Top, Workington, Cumberland, by will bequeathed £1000 to the Cumberland Infirmary, Carlisle, £1000 to the Workington Infirmary, and £300 to the Cumberland Sanatorium for Consumptives, to be applied towards securing a bed there for Workington for four years.—Mrs. Hamlyn of Clovelly Court has given 600 guineas to endow a bed in the Bideford (Devon) Infirmary in memory of her late husband.—Sir Alexander Wilson has by will left £1000 each to the Sheffield General Infirmary and to the Sheffield Royal Hospital and £500 to the Sheffield Children's Hospital.—Mrs. Emma Cadbury has, among other bequests, left by will £500 to the English Hospital at Jerusalem.—The honorary secretaries of King Edward's Hospital Fund for London have received from the executors of the late Lieutenant-General G. E. Baynes the sum of £10,000, being a second payment on account of the residuary estate bequeathed by the deceased to the fund.—Through Mr. A. Pearce Gould a donation of 100 guineas has been received by the secretary of the Middlesex Hospital Cancer Research Fund from Mr. A. J. R. Carlill.

INSURANCE AGAINST SICKNESS.—Mr. Oppenheimer, British Consul-General at Frankfort, in his annual report to the Foreign Office mentions that 'in Germany insurance against sickness is legally compulsory for all industrial workers, artisans, apprentices, and technical and commercial employees with an annual wage not exceeding 2000 marks. This insurance embraced during the first year of its existence 4,500,000 of insured and the number has since risen to 12,000,000. 20,000 offices, chiefly "local" and "factory" fund offices, carry out the practical work of this insurance, the minimum benefits of which are: (1) free medical treatment and supply of remedies (including spectacles, &c.); (2) from the third day of illness onward, sick money (daily at least half of the daily wage), or home treatment and half of the sick money paid to relatives. The majority of these offices also pay for at least six weeks' monetary assistance to women in child-bed, and in case of death, as death money, a sum amounting to 20 times the average daily wage. The obligation of these offices under this heading extends to six months, beyond which other branches of insurance law come into operation. The premiums of this insurance are paid jointly by employers and employees, the insured paying two-thirds and the employers one-third. On an average each case of sickness, combined with inability to earn daily wages, entails to the office an expenditure of 50 marks. Since their foundation these offices have paid in 60,500,000 cases of sickness (representing over 1,000,000,000 days of sickness) 2,500,000,000 marks. In 1904, the latest year for which detailed figures are available, the number of days of sickness compensated amounted to 90,000,000 and the sums paid were: for sick money, 106,000,000 marks; for home treatment of sick, 31,000,000 marks; for medical attendant and remedies, 85,000,000 marks; for payments to women in child-bed, &c., 4,500,000 marks; and for death money, &c., 10,500,000 marks: total, 237,000,000 marks.

from professional and official bodies interested. It was agreed that the Plumbers' Company is still to retain a large share in the management of the new body. The work of the plumber is so intimately associated with questions of public health that the public will be gainers by thus raising the new organisation above any exclusively trade interest and this its continued association with the Plumbers' Company insures. Apparently the recent preference shown in the employment of registered men by many of the water companies, municipal authorities, and others, has led the trade, as a whole, to see that certified efficiency is not without its advantages. The enlarged representation will doubtless stimulate registration and may lead to some statutory recognition. A general council, composed of masters, men, and representatives of the Plumbers' Company, is to be created, which will elect an executive committee, having full control of registration, finance, and all matters relating to the new organisation. We have previously on several occasions alluded to the expediency of legislation to enforce the registration of plumbers and are pleased to see that the movement in its favour has received such material strengthening by the coöperation of the trade as a whole.

GASTRIC CANCER PRODUCING GASTRO-CUTANEOUS FISTULA.

IN the *New York Medical Journal* of July 13th Dr. A. E. Taussig has reported a case of a very rare condition—gastro-cutaneous fistula. A man, aged 53 years, came under observation on Nov 14th, 1906. In the summer of 1905 he began to suffer from a dull ache in the epigastrium, especially after eating. About Christmas a tumour could be palpated in the epigastrium, and in the following June exploratory laparotomy was performed by a local practitioner. Nothing further was done and the wound healed by first intention. He rapidly grew weaker and about the end of July a growth appeared in the region of the umbilicus. When Dr. Taussig saw him he was greatly emaciated, very cachectic, and white haired, and looked like a man 80 years of age. His temperature varied irregularly from normal to 101° F. He took only liquid food, but in sufficient quantity and with relish. In the epigastrium was a laparotomy scar extending along the middle line to the umbilicus, where it ended in a raw, granulating mass of about the size of a small fist and hard. The entire epigastrium was filled by a hard, nodular, immoveable tumour, apparently adherent to the parietes. A course of alcohol injections into the mass of ten drops of 95 per cent. alcohol was begun. After the first injection the centre of the mass became necrotic, forming a funnel-shaped depression. On removing the dressing after the second injection the gauze was found soaked with milk and a fistula through which a probe could be passed into the stomach was found. All the food and water subsequently flowed out of the opening, milk being passed unclotted. 24 hours after the establishment of the fistula death occurred. The necropsy showed a hard, nodular mass on the anterior aspect of the stomach joined by a thick, cylindrical bridge to the umbilical tumour. On opening the stomach the mass was seen to project into its lumen. About the centre of the infiltrated wall of the stomach was an opening large enough to admit the little finger. This opening soon narrowed into a tortuous fistula through which a probe could be passed to the opening above described. On opening the fistula it was seen to be lined with smooth hard cancerous tissue; there were no signs of an abscess anywhere. There were no metastases and apparently no glandular induration. Microscopically the tumour showed the characteristics of an adeno-carcinoma. Gastro-cutaneous fistula is a very rare condition and other causes of it are perforation of a gastric ulcer which gives rise to an abscess that eventually opens externally and tuberculous peritonitis causing perforation both into the stomach and externally. In 1858 Murchison carefully searched the records of three centuries and was able to find reports of only 25 cases of gastro-cutaneous fistula, of which 12 were due to gastric ulcer, six to trauma, one to necrosis of ribs, and six to gastric cancer. Since that time 18 more cases due to gastric cancer have been reported, making 24 in all. In 16 food passed through the fistula and in eight the opening was too small to permit this. In two of the latter, however, gas escaped from the stomach. The fistula occurred spontaneously in 16 cases and was produced by incision of a bulging abscess in the other eight. These fistulas may be produced in two ways. An abscess may form, usually between the stomach, liver, and colon on the one side, and the abdominal wall on the other. Usually the abscess is produced by gastric perforation, but sometimes a large abscess develops and perforates into the stomach secondarily. Sooner or later, if the patient survives and if the abscess does not discharge into the colon or pleura, it produces external bulging, usually in the epigastrium, and either ruptures spontaneously or is incised. Less frequently there appears to be no abscess formation at all; the gastric tumour becomes adherent to the abdominal wall, grows through it and appears externally, usually at the navel, as a fungous mass. The central portion becomes necrotic, and the necrotic process extends both to the gastric and the parietal ends of the mass and a fistula lined by cancerous tissue results. A complete gastric fistula may discharge only pus in consequence of the narrowness of the lumen or on account of its tortuous course. The dimensions of the external orifice vary, sometimes hardly admitting a probe, sometimes being over an inch in diameter. Death usually soon follows, the interval varying from 24 hours (in the case reported above) to 13 months (in a case recorded by Murchison).

MYIASIS IN ALGERIA.

AN interesting study in parasitism is afforded by the observations of Dr. Edmond Sergent and Dr. Etienne Sergent on "Thim'ni," a form of myiasis occurring in Algeria, in a paper published in the *Annales de l'Institut Pasteur* of May 25th. For some years past they had noticed an affection of the face common among the shepherds of the mountains of Kabylie. The condition appears to be caused by the larvæ of the Œstrus ovis, which usually attacks sheep. The native name for this fly is "Thim'ni" and the same name is applied to the condition produced by its larvæ. It haunts the pasturages on the ridges and never descends to the villages. It deposits its ova while in flight, without settling, upon the eyes, the nostrils, or the lips of the shepherds, especially those who have eaten of the fresh sheep or goat's cheese. The condition is likewise found in dogs which are also fed upon cheese. If the ova are deposited upon the eye there is severe smarting, vision becomes impaired owing to the swelling of the conjunctivæ, and active white larvæ move over its surface. When they are deposited in the nostrils the pain is very great; and there are severe frontal headache preventing sleep, itching about the frontal sinuses, and a continual serous discharge from the nose. If the lips are the site of the affection inflammation extends to the throat and deglutition becomes difficult and painful, while cough is troublesome. Similar conditions are produced in dogs. The affection lasts from three to ten days and cure is always effected. The treatment adopted by the natives is in the case of the eye to remove the larvæ with a small piece of linen, for the nose to smoke tobacco or to snuff with it, and for the throat to gargle with an infusion of tobacco, onion, garlic, or pimento. The fly is difficult to secure, but the writers were able to find it in the very hot weather flying

Member suggests. In the last three months (April to June) seven accidents occurred. Everything that is possible is being done by the companies to devise means for preventing skidding.

Sanatoriums in Ireland.

Mr. HUGH LAW asked the Chief Secretary to the Lord Lieutenant of Ireland whether the Irish Local Government Board proposed to take any steps to carry out such recommendations of the Viceregal Commission on the Poor-law as did not require legislation; and in particular whether it was intended to build any sanatoriums for the treatment of consumption, or to adapt for the purpose any existing buildings.—Mr. BIRRELL replied: If the local authorities concerned should desire that effect may be given to any particular recommendations of the Viceregal Commission which can be carried out under the existing law the Local Government Board will give prompt and favourable consideration to the matter. Sanatoriums for the treatment of consumption can be provided under the existing law with the assent of the district councils. I may add that the Government are anxious that such administrative changes as can be now made should be undertaken without delay and are considering what steps may be taken with that object.

Tuberculous Meat and Milk.

Mr. FIELD asked the President of the Local Government Board whether he could state if the returns compiled by the Registrar-General were so framed as to give the number of deaths alleged to be attributable to the eating of cooked tuberculous meat and drinking uncooked tuberculous milk, and whether the infantile mortality was specified with regard to those alleged causes.—Mr. BURNS replied: The reply to the question is in the negative.

Haffkine's Prophylactic.

Sir WILLIAM COLLINS asked the Secretary of State for India whether he proposed to institute any further inquiry into certain deaths from tetanus in the Punjab consequent on the employment of Mr. Haffkine's prophylactic against plague or whether he accepted the conclusions of the Jenkins' Commission and of the Lister Institute as final; what action he proposed to take in regard to the further use of Mr. Haffkine's prophylactic and, if it was to be employed in the future, to which standard would it be required to conform; and whether Mr. Haffkine was to be reinstated or not.—Mr. MORLEY replied, by written answer: After giving the case my careful attention I am not prepared to institute another inquiry into a question which has been exhaustively examined by two impartial and independent bodies, and respecting which no conclusion can be arrived at with absolute certainty. The prophylactic continues to be manufactured at the Bombay Plague Laboratory. As is stated in the Government of India Press notice, dated Dec. 13th, 1904, the "standard method" of preparing the fluid has been reverted to, the fluid being sterilised by methods approved by the Indian Plague Commission and containing the requisite proportion of carbolic acid. The latest report of the laboratory states that inoculation is now extensively employed without any untoward results and I do not propose to take any action with regard to it. Mr. Haffkine's position was explained in the answer which I gave to the question asked by the honourable Member on March 19th, 1937. If he elects to return to India he will be employed on research work at a salary equal to that of which he was in receipt when he left India.

Medical Inspection of School Children.

After 11 o'clock at night,

Mr. MCKENNA moved the second reading of the Education (Administrative Provisions) Bill, which contains a clause relating to the medical inspection of school children. In intimating that if in committee any proposal contained in the Bill was objected to by the official opposition he would not proceed with the clause containing it, the right honourable gentleman said that Clause 10, which related to the medical inspection of school children, was the same clause as was introduced as a separate Bill by Mr. Walter Rea. That Bill had already received the complete approval of the House and was now awaiting third reading. For that reason he need not enlarge on Clause 10, which he hoped would receive the support of all parties in the House.

Sir WILLIAM ANSON said he most cordially supported the clause with regard to medical inspection.

Sir HENRY CRAIK, in criticising the various provisions of the Bill, said that if they were to throw upon local authorities the duty of inspecting school children in this respect and were to make that inspection effective they must give systematic direction and force to the work from the central department. If this was to be a Government scheme it ought to be a scheme much more perfect and scientific and more on a level with the provisions which existed in other countries.

Sir FRANCIS POWELL expressed a hope that the clause providing for medical inspection would become law this session.

The Bill was then read a second time.

THURSDAY, AUGUST 1ST.

Defaulting District Councils.

Mr. WEIR asked the President of the Local Government Board to state the names of the 12 district councils against which complaints were made during the years 1905 and 1906 in respect of default in the performance of their duty as required under Section 299 of the Public Health Act, 1875.—Mr. BURNS replied (by written answer): The names of the district councils whose cases were dealt with in the two years are as follows: In 1905, Dunmow rural, Eastbourne rural, Epsom rural, Penybont rural, and South Darley urban; and in 1906, Bromley rural, Cricklade and Wootton Bassett rural, Dunmow rural, Eastbourne rural, Hebburn urban, Lymington rural, and Rye rural. The cases of the Dunmow and Eastbourne rural district councils, which were partially dealt with in 1905, were further dealt with in 1906.

The Carshalton Hospital.

Mr. COOPER asked the President of the Local Government Board what was the annual amount of the interest, sinking fund, and cost of maintenance of the hospital for convalescent fever patients erected by the Metropolitan Asylums Board at Carshalton; whether the consent of the Local Government Board had to be obtained before the hospital could be erected; if so, whether any inquiry was made by the Local Government Board into the necessity of such hospital, and also the suitability of the site; and whether, as the hospital was unused, and there was great want of asylum accommodation in the county of London for imbecile and harmless senile lunatics, he would consider the advisability of requiring the Metropolitan Asylums Board using this hospital for such a purpose.—Mr. BURNS furnished the following written reply: The annual charge in respect of the items referred to is in round sums as follows:—Interest, £7500; repayment of principal, £8000; cost of maintenance (about), £2000. The debt is repaid by equal annual instalments of principal, so that the charge for interest diminishes each year. The consent of the Local Government Board had to be obtained to the erection of the hospital. Before any consent was given a public inquiry was held by inspectors of the Board, at which the need for the hospital and the suitability of the site were considered. The question of the use of the hospital for other purposes than that for which it was provided has not been lost sight of either by the Board or the managers, and it will be again considered as soon as circumstances permit, but until the existing prevalence of fever has abated it is thought desirable that the accommodation afforded by this hospital should be held in reserve. I have promised to continue to give attention to the matter, but meanwhile I am glad to learn that the demands on the managers in respect of imbeciles and harmless senile lunatics are not such as to point to any great want of accommodation for this class at the present time.

The Belfast Health Commission.

Mr. SLOAN asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that no member of the Health Commission sitting at Belfast was a veterinary surgeon or other person equally qualified to examine meat and dairy inspectors, with the result that the Commission had been unable to enter fully into the diseases of animals transmissible to man; whether, seeing the interest the public were now taking in the necessity of pure food and milk, he could see his way to have a veterinary surgeon or some other person with equal qualifications appointed as Local Government Board inspector to advise local authorities on such matters; and if not would he consider the advisability of transferring this work to the veterinary branch of the Board of Agriculture.—Mr. BIRRELL replied (by written answer): It is the fact that no veterinary surgeon has been appointed to the Commission referred to, but the two Local Government medical inspectors and the medical officer of health of Glasgow who are on the Commission appear to be eminently fitted to deal with questions of milk- and meat-supply. Local authorities have power to appoint as inspectors veterinary surgeons to advise them upon these questions. I am not aware of any reason for transferring public health duties to the Department of Agriculture.

Food and Meat Inspection in Ireland.

Mr. SLOAN asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to a meeting of the Royal Sanitary Institute held a few days ago at Douglas, where Sir Charles Cameron, medical officer of health of Dublin, stated that the central body should itself carry out, or insist on the local authorities carrying out, a more complete inspection of food and meat; and whether, in view of the resolution that was passed at a meeting of the Veterinary Medical Association in Belfast on July 26th to the effect that such inspection should be conducted only by trained veterinarians he could say what steps, if any, he proposed to take in the matter.—Mr. BIRRELL gave the following written reply: The honourable Member has sent to me a newspaper report of the proceedings referred to but the official report has not yet been issued. The Local Government Board has received a copy of the resolution passed by the Veterinary Surgeons' Association in Belfast. Under the law as it stands the appointment of inspectors of food and meat rests with the local authorities and they have full power to appoint veterinary surgeons in that capacity.

FRIDAY, AUGUST 2ND.

Public Health (Regulations as to Food) Bill.

On the motion for the second reading of the Public Health (Regulations as to Food) Bill, Mr. G. J. COOPER moved as an amendment that the Bill should be read a second time this day three months. He went on to say that it would make a drastic change in the law by transferring to the Local Government Board the whole control of the regulations dealing with food. It would place all food except drugs and all drinks except water under regulations to be made by the Local Government Board. There was no security that those regulations would be submitted to Parliament.

Mr. WATT, in seconding Mr. Cooper's amendment, regretted that the Local Government Board did not propose to give any notice as to any one of the regulations for the destruction of food, however drastic, which they should make under the Bill. They would deal with the importation, preparation, storage, and distribution of articles of food and drink without giving notice to the people affected. Such a principle he believed had been seldom assented to by the House of Commons. He was strongly of opinion that such regulations should be laid before both Houses of Parliament for 40 days before they came into effect.

Mr JOHN BURNS asked the House to give a second reading to this useful, necessary, and too long delayed measure. It would make up deficiencies in existing Acts of Parliament by giving the Local Government Board controlling powers over the condition, preparation, storage, and distribution of human food which was peculiarly liable to become unsound. At present the Public Health Acts empowered a medical officer of health or an inspector of nuisances to examine meat or other articles of food if exposed or deposited for purposes of sale or in preparation for sale, and a magistrate could condemn such food if it were diseased or unwholesome. Penalties might be imposed on the persons in whose premises it was found. That provision, however, was insufficient to protect public health. The defect in the existing law was that foods on their way to be sold or prepared could not be touched, because they were not, in the language of the Act, "exposed for sale" for human consumption. The position could be best illustrated by a concrete instance. At the conclusion of the South African war a large quantity of tinned foods sent out for the use of the army was sold. So bad was the reputation of this food in South Africa that no one would think of touching it. It was shipped back to England and although it was known to be in a shocking condition it could not be seized at the port of landing because it was not exposed for sale. It came to London, and to the credit of the firm who originally prepared it and sold it, and who, of course, were not responsible for the condition into which it had fallen by lapse of time, they informed the Local Government Board of the circumstance, because they feared that if the food were sold with their name on the packages their reputation would suffer enormously. The aspects of botany that are often not seriously regarded. Perhaps the most interesting part of his discourse was that which dealt with the examples of interference with the developmental processes. "Disease," he said, "represents the necessary outcome of a disturbance, however introduced, into the course of metabolism which diverts it from the normal channels." Pathology thus recognises that the explanation and the consequent control of disease lie ultimately in the correct appreciation of the cellular reactions as the result of their experimental study. He believed that we have gained enough insight into the chemistry and physics of the living processes to warrant us in hoping that we shall penetrate a good deal deeper still. When the conditions for the manifestation of life and all that it implies are satisfied, what will be produced depends partly on the structure of the apparatus itself (i.e., on the hereditary organisation), partly on the nature of the substances fed into the apparatus, and finally, on the physical conditions under which it is working. The goal will not be reached, he added, until we have solved the problem as to the nature of organisation itself.

"What is an atom?" formed the momentous issue at one time in the section of Mathematical and Physical Science, where were gathered together both physicists and chemists each claiming for this mighty particle an electrical or chemical definition according to whether the claimant was chemist or physicist. Sir OLIVER LODGE did not mince matters and at once acknowledged that he was prepared to champion the electric theory of matter, regarding it as a working hypothesis of the most valuable kind in providing a guide to experiment, and he trusted it would long continue to hold the field and to stimulate the work of many explorers. He regretted that Lord Kelvin had not accepted this theory but had shown a disposition of late "to destroy his own children." Sir WILLIAM RAMSAY acknowledged the great light which physicists had thrown on the question but as a chemist he was more interested in the proximate than in the ultimate construction of the atom. Later, Sir William Ramsay referred to his experiments with radium emanation (already described in THE LANCET) in which there appeared to be distinct reason for believing that the energy of the emanation had "degraded" copper into lithium.

The atomic theory was also discussed by Professor A. SMITHELLS in his opening address to the section on Chemistry. He did not admit that the investigations of radio activity had entailed anything like an unsettlement of their scientific articles of faith. The atomic theory stood to-day as an indispensable instrument for productive chemical work, it had neither had its day nor ceased to be. The hard indivisible ball of specific substance had served chemistry well, better, perhaps, than the bells and vortex rings of the physicist. Professor Smithells discoursed also on the subject of flame, a study to which he has given special attention and added great interest. He did not think there could be any doubt that the luminosity of the hydrocarbon flame was due essentially to the separation within the flame of minute solid particles of what was practically carbon.

In the Biological Section Mr. OSWALD H. LUTHER read a paper on the Teaching of Biology in Schools. He said that as a training in experiment, in precision, and in exact reasoning biology perhaps has not the advantages of physics and chemistry, but in quickening the powers of observation it was, he thought, unsurpassed by any of the sciences. As to the contention that anatomy and physiology are "nasty" and even indecent and not fit subjects of education *virginibus puerisque* he asks, "Are we to do all we can to encourage the study of animal life and then deny all information and guidance on phenomena (the processes of reproduction which it is proposed should be left out of the curriculum) which are bound to come under observation as though these were something unholy and unclean?" He contended that curiosity on these matters is natural and inevitable and therefore he submitted that it is far better—it is best—that this legitimate curiosity should be satisfied and instructed in a clean, wholesome, and scientific way than by any other means, and it is only by such a course that a reverent respect for the whole body, whether of brute or man, can be gained.

We have attempted but a brief sketch of part of the proceedings of the British Association this year, but we have said enough to show that the subjects brought under discussion were completely cosmopolitan in character.

FORTY-NINTH ANNUAL REPORT OF THE GENERAL BOARD OF COMMISSIONERS IN LUNACY FOR SCOTLAND.

THERE were 17,593 insane persons under official cognisance on Jan. 1st, 1907: of these 2563 were maintained from private sources, 14,979 by parochial rates, and 51 at the expense of the State, the total increase during the year being 143. The following figures indicate the difference in the manner of distribution of registered lunatics compared with those on Jan. 1st, 1906. In Royal asylums there is a decrease of 12 private patients and 124 pauper patients. In district asylums there is an increase of 31 private patients and of 401 pauper patients. In private asylums there is a decrease of 17 in the number of private patients. In parochial asylums there is an increase of 25 pauper patients. In lunatic wards of poorhouses there is a decrease of 168 pauper patients. In private dwellings there is an increase of seven private patients and of 22 pauper patients. In the year 1905 there was a decrease in the number of pauper patients in 15 counties. In the year 1906 there was a decrease in 18 counties. These counties include large industrial centres such as Aberdeenshire, Forfarshire, and Fife. The total decrease in the number of pauper lunatics in the 18 counties above mentioned amounts to 95, as compared with a decrease of 59 in 15 counties during the previous year. This decrease is more than counterbalanced by an increase of 262 in the remaining 15 counties, but of this increase 77 per cent. is contributed by the counties of Edinburgh, Lanark, Renfrew, and Stirling. Since 1858 the number of lunatics on the register of the Board has increased 197 per cent., while the increase of the population during the same period has been 56 per cent. This is a fact, however, which has no bearing upon the question of the increase of insanity, as the provision made for the insane in 1858 was altogether inadequate and the Act passed in the previous year was to remedy this defect and to place a larger number of the insane upon the Board's register. The Commissioners report with great satisfaction that the statistics of the past two or three years seem to show that a point has been reached beyond which no considerable increase of registered lunacy need be looked for, except that which corresponds to the increase of the population. The largest actual number ever placed on the register in one year occurred in 1902, when it was 3660. The number was 3658 in 1904; 3449 in 1905; and 3370 in 1906. When it is considered that these decreases have occurred in a population which is estimated to be growing at a considerable rate, the figures are significant. And, further, what is even more significant is the fact that the numbers registered for the first time for the combined classes show a continuous fall during the past four years, and the largest fall occurred in the year 1906. The number of voluntary patients admitted into the asylums during 1906 was 103, which is about 20 over the average number so treated, and the Commissioners speak highly of the value of this form of treatment. The recovery-rate taken from the recoveries per cent. of admissions, excluding transfers, is 41·2 for private patients, or about an average one, whereas for paupers there is a marked decrease. The *Commissioners account* for this by the increased use of the observation wards connected with parochial hospitals, which probably intercept a considerable number of persons suffering from passing attacks of mental disorder, many of whom in the absence of such wards would have been removed to asylums. The proportion of deaths per cent. of the numbers resident in all establishments is 9·1 for private patients and 9·5 for pauper patients. A licence was granted for the establishment of one new private asylum.

The establishments for the insane in Scotland arrange themselves in the following groups: (*a*) Royal and district asylums; (*b*) private asylums; (*c*) parochial asylums; (*d*) lunatic wards of poorhouses; (*e*) training schools for imbecile children; and (*f*) criminal department. Several pages of the report are devoted to matters concerning the various institutions above referred to.

The number of private patients who were provided for in private dwellings with the sanction of the board on Jan. 1st, 1907, was 133; one-third of these were in houses which possessed a special licence for the reception of not more than four patients, and two-thirds were placed singly in houses, which, having only one patient, require no licence.

Member suggests. In the last three months (April to June) seven accidents occurred. Everything that is possible is being done by the companies to devise means for preventing skidding.

Sanatoriums in Ireland.

Mr. Hugh Law asked the Chief Secretary to the Lord Lieutenant of Ireland whether the Irish Local Government Board proposed to take any steps to carry out such recommendations of the Viceregal Commission on the Poor-law as did not require legislation; and in particular whether it was intended to build any sanatoriums for the treatment of consumption, or to adapt for the purpose any existing buildings.—Mr. Birrell replied: If the local authorities concerned should desire that effect may be given to any particular recommendations of the Viceregal Commission which can be carried out under the existing law the Local Government Board will give prompt and favourable consideration to the matter. Sanatoriums for the treatment of consumption can be provided under the existing law with the assent of the district councils. I may add that the Government are anxious that such administrative changes as can be now made should be undertaken without delay and are considering what steps may be taken with that object.

Tuberculous Meat and Milk.

Mr. Field asked the President of the Local Government Board whether he could state if the returns compiled by the Registrar-General were so framed as to give the number of deaths alleged to be attributable to the eating of cooked tuberculous meat and drinking uncooked tuberculous milk, and whether the infantile mortality was specified with regard to those alleged causes.—Mr. Burns replied: The reply to the question is in the negative.

Haffkine's Prophylactic.

Sir William Collins asked the Secretary of State for India whether he proposed to institute any further inquiry into certain deaths from tetanus in the Punjab consequent on the employment of Mr. Haffkine's prophylactic against plague or whether he accepted the conclusions of the Jenkins' Commission and of the Lister Institute as final; what action he proposed to take in regard to the further use of Mr. Haffkine's prophylactic and, if it was to be employed in the future, to which standard would it be required to conform; and whether Mr. Haffkine was to be reinstated or not.—Mr. Morley replied, by written answer: After giving the case my careful attention I am not prepared to institute another inquiry into a question which has been exhaustively examined by two impartial and independent bodies, and respecting which no conclusion can be arrived at with absolute certainty. The prophylactic continues to be manufactured at the Bombay Plague Laboratory. As is stated in the Government of India Press notice, dated Dec. 13th, 1904, the "standard method" of preparing the fluid has been reverted to, the fluid being sterilised by methods approved by the Indian Plague Commission and containing the requisite proportion of carbolic acid. The latest report of the laboratory states that inoculation is now extensively employed without any untoward results and I do not propose to take any action with regard to it. Mr. Haffkine's position was explained in the answer which I gave to the question asked by the honourable Member on March 19th, 1907. If he elects to return to India he will be employed on research work at a salary equal to that of which he was in receipt when he left India.

Medical Inspection of School Children.

After 11 o'clock at night,

Mr. McKenna moved the second reading of the Education (Administrative Provisions) Bill, which contains a clause relating to the medical inspection of school children. In intimating that if in committee any proposal contained in the Bill was objected to by the official opposition he would not proceed with the clause containing it, the right honourable gentleman said that Clause 10, which related to the medical inspection of school children, was the same clause as was introduced as a separate Bill by Mr. Walter Rea. That Bill had already received the complete approval of the House and was now awaiting third reading. For that reason he need not enlarge on Clause 10, which he hoped would receive the support of all parties in the House.

Sir William Anson said he most cordially supported the clause with regard to medical inspection.

Sir Henry Craik, in criticising the various provisions of the Bill, said that if they were to throw upon local authorities the duty of inspecting school children in this respect and were to make that inspection effective they must give systematic direction and force to the work from the central department. If this was to be a Government scheme it ought to be a scheme much more perfect and scientific and more on a level with the provisions which existed in other countries.

Sir Francis Powell expressed a hope that the clause providing for medical inspection would become law this session.

The Bill was then read a second time.

THURSDAY, AUGUST 1ST.

Defaulting District Councils.

Mr. Weir asked the President of the Local Government Board to state the names of the 12 district councils against which complaints were made during the years 1905 and 1906 in respect of default in the performance of their duty as required under Section 299 of the Public Health Act, 1875.—Mr. Burns replied (by written answer): The names of the district councils whose cases were dealt with in the two years are as follows: In 1905, Dunmow rural, Eastbourne rural, Epsom rural, Penybont rural, and South Darley urban; and in 1906, Bromley rural, Cricklade and Wootton Bassett rural, Dunmow rural, Eastbourne rural, Hebburn urban, Lymington rural, and Rye rural. The cases of the Dunmow and Eastbourne rural district councils, which were partially dealt with in 1905, were further dealt with in 1906.

The Carshalton Hospital.

Mr. Cooper asked the President of the Local Government Board what was the annual amount of the interest, sinking fund, and cost of maintenance of the hospital for convalescent fever patients erected by the Metropolitan Asylums Board at Carshalton; whether the consent of the Local Government Board had to be obtained before the hospital could be erected; if so, whether any inquiry was made by the Local Government Board into the necessity of such hospital, and also the suitability of the site; and whether, as the hospital was unused, and there was great want of asylum accommodation in the county of London for imbecile and harmless senile lunatics, he would consider the advisability of requiring the Metropolitan Asylums Board using this hospital for such a purpose.—Mr. Burns furnished the following written reply: The annual charge in respect of the items referred to is in round sums as follows:—Interest, £7500; repayment of principal, £6000; cost of maintenance (about), £2000. The debt is repaid by equal annual instalments of principal, so that the charge for interest diminishes each year. The consent of the Local Government Board had to be obtained to the erection of the hospital. Before any consent was given a public inquiry was held by inspectors of the Board, at which the need for the hospital and the suitability of the site were considered. The question of the use of the hospital for other purposes than that for which it was provided has not been lost sight of either by the Board or the managers, and it will be again considered as soon as circumstances permit, but until the existing prevalence of fever has abated it is thought desirable that the accommodation afforded by this hospital should be held in reserve. I have promised to continue to give attention to the matter, but meanwhile I am glad to learn that the demands on the managers in respect of imbeciles and harmless senile lunatics are not such as to point to any great want of accommodation for this class at the present time.

The Belfast Health Commission.

Mr. Sloan asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that no member of the Health Commission sitting at Belfast was a veterinary surgeon or other person equally qualified to examine meat and dairy inspectors, with the result that the Commission had been unable to enter fully into the diseases of animals transmissible to man; whether, seeing the interest the public were now taking in the necessity of pure food and milk, he could see his way to have a veterinary surgeon or some other person with equal qualifications appointed as Local Government Board inspector to advise local authorities on such matters; and if not would he consider the advisability of transferring this work to the veterinary branch of the Board of Agriculture.—Mr. Birrell replied (by written answer): It is the fact that no veterinary surgeon has been appointed to the Commission referred to, but the two Local Government medical inspectors and the medical officer of health of Glasgow who are on the Commission appear to be eminently fitted to deal with questions of milk- and meat-supply. Local authorities have power to appoint as inspectors veterinary surgeons to advise them upon these questions. I am not aware of any reason for transferring public health duties to the Department of Agriculture.

Food and Meat Inspection in Ireland.

Mr. Sloan asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to a meeting of the Royal Sanitary Institute held a few days ago at Douglas, where Sir Charles Cameron, medical officer of health of Dublin, stated that the central body should itself carry out, or insist on the local authorities carrying out, a more complete inspection of food and meat; and whether, in view of the resolution that was passed at a meeting of the Veterinary Medical Association in Belfast on July 26th to the effect that such inspection should be conducted only by trained veterinarians he could say what steps, if any, he proposed to take in the matter.—Mr. Birrell gave the following written reply: The honourable Member has sent to me a newspaper report of the proceedings referred to but the official report has not yet been issued. The Local Government Board has received a copy of the resolution passed by the Veterinary Surgeons' Association in Belfast. Under the law as it stands the appointment of inspectors of food and meat rests with the local authorities and they have full power to appoint veterinary surgeons in that capacity.

FRIDAY, AUGUST 2ND.

Public Health (Regulations as to Food) Bill.

On the motion for the second reading of the Public Health (Regulations as to Food) Bill, Mr. G. J. Cooper moved as an amendment that the Bill should be read a second time this day three months. He went on to say that it would make a drastic change in the law by transferring to the Local Government Board the whole control of the regulations dealing with food. It would place all food except drugs and all drinks except water under regulations to be made by the Local Government Board. There was no security that those regulations would be submitted to Parliament.

Mr. Watt, in seconding Mr. Cooper's amendment, regretted that the Local Government Board did not propose to give any notice as to any one of the regulations for the destruction of food, however drastic, which they should make under the Bill. They would deal with the importation, preparation, storage, and distribution of articles of food and drink without giving notice to the people affected. Such a principle he believed had been seldom assented to by the House of Commons. He was strongly of opinion that such regulations should be laid before both Houses of Parliament for 40 days before they came into effect.

Mr John Burns asked the House to give a second reading to this useful, necessary, and too long delayed measure. It would make up deficiencies in existing Acts of Parliament by giving the Local Government Board controlling powers over the condition, preparation, storage, and distribution of human food which was peculiarly liable to become unsound. At present the Public Health Acts empowered a medical officer of health or an inspector of nuisances to examine meat or other articles of food if exposed or deposited for purposes of sale or in preparation for sale, and a magistrate could condemn such food if it were diseased or unwholesome. Penalties might be imposed on the persons in whose premises it was found. That provision, however, was insufficient to protect public health. The defect in the existing law was that foods on their way to be sold or prepared could not be touched, because they were not, in the language of the Act, "exposed for sale" for human consumption. The position could be best illustrated by a concrete instance. At the conclusion of the South African war a large quantity of tinned foods sent out for the use of the army was sold. So bad was the reputation of this food in South Africa that no one would think of touching it. It was shipped back to England and although it was known to be in a shocking condition it could not be seized at the port of landing because it was not exposed for sale. It came to London, and to the credit of the firm who originally prepared it and sold it, and who, of course, were not responsible for the condition into which it had fallen by lapse of time, they informed the Local Government Board of the circumstance, because they feared that if the food were sold with their name on the packages their reputation would suffer enormously. The diminution of private enterprise but rather by increased activity on the part of societies and individuals.

Papers were also read on House Inspection and on the Land Question.

THE INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS: COMMITTEE MEETING AT LONDON.

(FROM OUR SPECIAL COMMISSIONER.)

ON Friday evening, August 2nd, members of the British Association of the Medical Press were in attendance at the Langham Hotel to receive the representatives of the medical press associations of other countries. Unfortunately there were disappointments at the last hour. The Dutch delegate, for instance, was prevented from attending and there was not time enough to find a substitute. The Italians had promised to send three delegates, but in any case they did not arrive in time. There were consequently representatives from Austria, Germany, Belgium, France, Norway, and Great Britain, only six nationalities, and this is an illustration of one of the great difficulties that beset this in common with all other international associations. A society to be really international must be governed by a committee the members of which live in the country they represent and who have therefore to travel long distances so as to meet each other. Thus in regard to the present organisation it will be remembered that its creation was definitely decided at the International Congress of the Medical Press held in Paris in 1900. Then in 1902 an international conference was convoked at Monaco to draw up the statutes of the proposed association. These were adopted by the Second International Congress of the Medical Press held at Madrid in 1903 and in September of the same year the committee of the association met at Brussels. In 1905 the committee came together again at Berne and in 1906 a general assembly of the association was held at Lisbon. Finally this year the committee has met in London. Next year it will go to Berlin and the year following there will be the next general assembly of the association at Budapest. It is necessary, therefore, to be a somewhat experienced and hardened traveller to follow the society in all its peregrinations and it is not surprising if there is but a small attendance at these meetings.

On the morning of August 3rd the delegates met at the rooms of the Medical Society of London which is next door to their hotel. Professor POSNER of Berlin, President of the Association, took the chair, and, after expressing his thanks to the British members for organising their reception, called upon the general or international secretary of the association, Dr. R. Blondel of Paris, to present a report on the general situation.

Among other details given by Dr. BLONDEL he explained that they had been successful at Lisbon in some of their work. One of the objects of the association was to see that all the necessary facilities and privileges were provided for members of the association who attended congresses so that they might do their difficult work with as much ease as possible. At the International Congress of Medicine held at Lisbon in April, 1906, the Portuguese organisers of the medical congress gave to the medical press all that they requested. They also printed a report of the proceedings which was now distributed among the delegates present. This was the first effect produced by the association and they were going to get similar advantages for the International Congress to be held at Budapest in 1909. The next question was that of medical papers (so-called) issued by manufacturers and distributed gratuitously. Nothing definite had been achieved. This had become a real plague in France. Firms preferred to spend £1000 a year in issuing a publication of their own rather than spending the same amount in giving advertisements to genuine medical journals. Consequently the income from advertisements was decreasing. A committee had been appointed to deal with the matter but it could not agree as to a formula. What constituted a gratuitous publication? All papers could pretend to have purchasers. Now in France if the advertisements fell off they would have to raise the sale price or subscription, but then the subscribers would cease to subscribe, so that medical papers were menaced with extinction. Doubtless, if it had become a matter of sufficient advantage to be a member of the Association of the Medical Press something might be done by excluding those who contributed to these gratuitous journals. As matters now stood, however, such authors would not care if they were excluded. In regard to copyright nothing new had occurred since the meeting of the committee at Berne. It was then decided that authors should not publish the same paper at the same time elsewhere, even in another country and in another language, without giving due notification that they intended to do so. Still, speaking of the French Medical Press Association, Dr. Blondel said that many of its members did not appreciate the use of the International Association. Some of them had even proposed not to subscribe, but this occasioned very energetic protests, the President going so far as to say he would resign if such a proposal were carried. The suggestion was easily set aside. The fact nevertheless remained that the association had not yet succeeded in rendering services of such an indisputable character as to make its usefulness generally recognised. Much more had to be done. The International Association struggled for others who did not support the association. Dr. Blondel explained that illness had, at the last moment, prevented one of the three delegates to which France was entitled from being present. The Russians still refused to answer letters. There was the disturbed state of the country and the fear of compromising themselves politically to account for their silence, but he thought that perhaps the blunder committed in 1900 had not yet been forgiven. They had unintentionally received a person who was not properly delegated; but the real delegate, instead of attending, said it was too hot and went off to Trouville. Also the Russians are as bad as the Americans in the infringement of copyright and that might account for their absence. As for the Italians, they were still quarrelling among themselves with deplorable persistency and energy. The general secretary had written four times, registering the last two letters, to Dr. Ascoli, who was one of the Vice-Presidents of the International Association, and yet he had received no answer. Dr. Bossi replied and promised to come and two other Italians were to accompany him but they had not arrived. Evidently it would be necessary to wait till the Italians had finished quarrelling and had collected some funds. All countries were not like England with its two great leading journals working harmoniously together. Something would have to be done to secure a Hungarian representation, though as yet there was not even a national organisation in Hungary. The Bohemians and other nationalities united to the Austrian Empire might come in.

Dr. DOLÉRIS, the second French delegate, also spoke at some length, confirming much of what Dr. Blondel had said. There were in France the druggists' press and the genuine press, and it was a mistake to despise the former. There was one firm interested in ferruginous products that published a paper often containing good articles written by able men who were well paid. The editor received £400 a year. Evidently such things should not be, and medical men who wrote for manufacturers of drugs should not be admitted into the Association of the Medical Press. In France they had formerly been very severe but they had become lax and it would now be necessary to purify their ranks.

Professor POSNER of Berlin reported for Austria and Germany. The organisation of the medical press published in the German language had progressed. At first the work was slow but now they had enrolled all the editors of the archives as well as of the journals. Thus they had become a force and this they proved by taking action against authors who were poisoning public opinion. There were medical men who offered to sell to manufacturers of medicaments articles describing the cures they were supposed to have effected by the use of one of the manufacturer's drugs. If the article was refused they simply changed the name of the drug and tried another manufacturer. They might offer to give the details of, for instance, a hundred cases for a thousand marks. The German Association of the Medical Press had approached the manufacturers. They were well received and supplied with documents that left no doubt whatsoever as to the venal character of the practices described. A list had therefore been drawn up comprising more than 40 names, and these were not all Germans, but there were Austrians, Italians, and others anxious to sell their services to the German druggists. The German Association of the Medical Press has decided not to publish any contributions from these persons. Further, should any paper insert an article from these writers that paper will not be admitted into the association. This may result in their having to expel from their

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary £100 per annum, with board and lodgings.

Bristol Royal Infirmary.—Resident Junior House Surgeon; also Resident Casualty Officer. Salaries at rate of £50 per annum, with board, lodging, and washing.

Bury Infirmary.—Junior House Surgeon. Salary £80, with board, residence, and attendance.

Buxton, Derbyshire, Devonshire Hospital.—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

Cairo, School of Medicine (Egyptian Government, Ministry of Education).—Assistant to the Professor of Pathology. Salary £E. 320 per annum.

Cancer Hospital, Fulham-road, S.W.—Two Assistant Anæsthetists. Honorarium of 25 guineas each.

Chelsea Hospital for Women, Fulham-road, S.W.—Clinical Assistant.

Colchester, Essex and Colchester General Hospital.—House Physician. Salary £80 per annum, with board, residence, and washing.

Devon County Asylum.—Assistant Medical Officer. Salary £140, with board, apartments, and laundry.

Devonport, Royal Albert Hospital.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, &c.

Dover, Royal Victoria Hospital.—House Surgeon, unmarried. Salary £100 a year, with board, lodging, and washing.

Egyptian Government, Kasr-El-Ainy Hospital.—Resident Medical Officer. Pay £250 a year, with quarters, servants, washing, coals, and light.

Glasgow District Asylum, Woodilee, Lenzie.—Assistant Medical Officer. Salary £135 per annum, with board, lodging, &c.

Gloucester, General Infirmary and the Gloucestershire Eye Institution.—Assistant House Surgeon for six months. Salary at rate of £30 per annum, with board, residence, and washing.

Grimsby and District Hospital.—Resident House Surgeon. Salary £100 per annum, with board, lodging, and washing.

Huddersfield Infirmary.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

Hull, Royal Infirmary.—Casualty House Surgeon. Salary £50, with board and lodging.

Ipswich, East Suffolk and Ipswich Hospital.—Third House Surgeon. Salary £50 per annum, with board, attendance, and washing.

Liverpool Dispensaries.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

Loughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary £100 per annum, with rooms, attendance, board, and washing.

Manchester, Ancoats Hospital.—Resident House Physician.

Manchester Children's Hospital, Pendlebury.—Assistant Medical Officer (non-resident).—Salary £100 per annum.

Manchester, Monsall Fever Hospital.—Fourth Medical Assistant. Salary £100 per annum, with board, lodgings, and washing.

Northampton, Borough of.—Medical Officer of Health. Salary £400 per annum, rising to £500, with reasonable carriage expenses.

Prestwich, Manchester, County Asylum.—Junior Assistant Medical Officer, unmarried. Salary £150, increasing to £250, with board, apartments, and washing.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

Rochdale Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, and laundry.

Royal Institute of Public Health.—Demonstrator of Comparative Pathology and Bacteriology.

Sheffield Royal Infirmary.—Junior Assistant House Surgeon. Salary £65 per annum, with board and residence.

Southampton, Royal South Hants and Southampton Hospital.—House Physician. Salary £100 per annum, with rooms, board, and washing.

Southport Infirmary.—Residents' Senior House Surgeon. Also Junior House and Visiting Surgeon, unmarried, for six months. Salary of Senior at rate of £90 per annum, and of Junior £70 per annum, with residence, board, and washing.

Stockport Infirmary.—House Surgeon. Salary £100 per annum, with board, washing, and residence. Also Junior Assistant House and Visiting Surgeon. Salary £40 per annum, with board, washing, and residence.

West London Hospital, Hammersmith-road, W.—Two House Physicians and Three House Surgeons, tenable for six months.

Worcester County and City Asylum.—Assistant Medical Officer, unmarried. Salary £140, rising to £160, all found.

York County Hospital.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Cheltenham, in the county of Gloucester.

Births, Marriages, and Deaths.

BIRTHS.

Lister.—On August 4th, at Devonshire-place, W., the wife of W. T. Lister, F.R.C.S., of a son.

Underhill.—On August 1st, at Castle View, Newport, I.W., the wife of S. V. H. Underhill, M.R.C.S., L.R.C.P., of a son.

Wells.—On July 27th, at Ashworth Mansions, Elgin-avenue, W., the wife of John H. Wells, M.B., B.S., of a son.

MARRIAGE.

McCrea—Watson.—On July 30th, at St. Mary's, Wargrave, John McCrea, B.A., M.B., B.Ch., to Alice Cradock, daughter of the late William Spencer Watson, M.B., F.R.C.S.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A LONDON JURYMAN AND THE SCOTCH FORM OF OATH.

At an inquest recently held at Stepney in the east of London considerable amusement was caused by the remarks of a juryman, evidently bewildered by the novelty of the position in which he found himself. A medical man who had been called to give evidence was sworn in the Scotch fashion, holding up his hand, whereupon the following dialogue ensued:—The juror: What's that for? Why can't he kiss the book like others (laughter)?—The coroner (Mr. Godding): That is the Scotch oath.—The juror: But he ain't a Scotchman (laughter).—Coroner: Anyone who prefers it may be sworn in that manner. In your second remark you are not quite correct, for the witness is a Scotchman.—The juror: Is he? Well he doesn't look like one.—The witness: The coroner is quite right.—The juror: Why, you don't talk like one either. The juror evidently expected a Scotchman to wear a kilt and talk Gaelic.

MICROSCOPICAL APPARATUS.

Microscopists will find a variety of useful hints in a descriptive catalogue of accessory apparatus for the microscope just issued by Messrs. R. and J. Beck, of 68, Cornhill, London, E.C. In addition to a profusion of illustrations there are directions for using some of the apparatus, such as the observing prism, which enables an object to be viewed directly with the eye and focussed in a micrographic camera at the same time, a finder for use on the ordinary plain stage, the Ehrlich eyepiece for use in making blood counts, various micrometers, and Grayson's test rulings up to 120,000 lines to the inch, and photographic cameras adapted both for the horizontal and the vertical position. At the end hints are given on general microscopic illumination.

AN INTERESTING ROYAL WARRANT.

Messrs. Alexander Robb and Co., the well-known manufacturers of Robb's Nursery Biscuits, have been appointed infant food manufacturers to the Royal Household of Spain under a special warrant from King Alfonso XIII., dated May 29th, 1907.

Ormond-street (2.30 P.M.), Tottenham (Gynæcological, 2.30 P.M.).

important question. He agreed with Lord Crewe in regard to what he had said about the medical inspection of schools. He had always been in favour of boys' brigades and cadet corps, for they taught the youth of the country the discipline which was always of use to them in after life. He agreed that the rifle should not take the place of games, but considered that the two should be combined.

Sir LAUDER BRUNTON then delivered his presidential address. After welcoming the delegates, he said that he was sure that the first duty which they would wish him to perform as their president was to voice their thanks to the King, Patron of the Congress, for the gracious welcome which they had received from him through his representative, Lord Crewe. It was through the King's personal interest in overcoming difficulties that the success of the Congress had been made possible. Its success would not be due only to the work which they trusted it would accomplish during the time of its sitting, but after it was over, for they hoped that arrangements would be made by which its work would become permanent and would be carried on in the intervals between successive Congresses. The First International Congress, which owed its origin to the enthusiasm and energy of Dr. Griesbach, whom they had the pleasure of seeing amongst them, held its first sitting three and a half years ago at Nuremberg. An invitation was sent from the Royal Sanitary Institute of London to ask the Congress to hold its second meeting here. A second invitation was also received to hold the Congress in Paris, but their French *confrères* withdrew their invitation with courtesy and grace on learning that ours had been previously received. They were met from every part of the civilised world, throwing aside every subject of disagreement, and were intent only on one common object—the health of the children. They all desired that their children should grow up healthy, strong, and happy and they were all anxious to take the best means at their disposal to obtain such a desirable end. In civilised communities the complexity of conditions sometimes led, and, indeed, had led, to mistakes in education, and the very meaning of the word had been forgotten, so that instead of drawing out and developing in every child all his possible powers of body and of mind education had degenerated into a system of cramming and cultivating one or two faculties of the mind, and especially that of memory, to the injury of others, while the condition of the body as the servant of the mind had to a certain extent been lost sight of in this country. They were now awakening to the necessity of attending to the body if the mind was to be developed. The great advantage of a Congress like this was that the systems employed in various countries were brought together and compared. One of the most important subjects of all in this respect was that of medical inspection in schools, because that was the keystone of physical education. Without it the defects of eyes, ears, nose, and teeth which affected individual scholars could not be ascertained, and so those children remained backward in their learning, suffering in their bodies and so much damaged in physique that they were unfitted for many occupations, could not enter the army, and went to swell the numbers of the criminal classes. Equally important were those hidden defects of heart and lungs which rendered the physical exercises, suitable for others, harmful and dangerous to the child with a weak heart, and made a child suffering from pulmonary tuberculosis unsuitable for school life and a source of danger to his companions. By the early recognition and isolation of infected children the necessity for closing schools might be, to a great extent, prevented, the spread of skin diseases completely checked, and even a fatal disease like diphtheria might be almost stamped out. The confinement and work in school had an exhausting effect upon many children who suffered in consequence from anæmia and debility. In order to prevent this it was necessary that the children should have as much fresh air and sunshine as possible. A most important departure in this respect was the recent establishment by the London County Council of a *Waldschule* or open-air school at Abbey Wood, where weakly children had the open air, rest, and abundant food necessary to restore them to health and strength. The necessity of separate training for children who were mentally deficient was already generally recognised. Separate schools for cripples were now being established, but while it was good to train them it was still better to prevent them from becoming cripples, and this could, to a great extent, be done by medical inspection. The technical training which the cripples at present received ought not to be limited to them, but ought to form a part of the regular teaching which would fit both boys and girls for their duties in after life. In many cases, where the deformity was slight, it might be cured by a proper system of physical exercise. Physical training of children in some countries was carried out by systematic exercise which developed the muscles, while in this country we depended more upon games. Both of these systems left something to be desired and the ideal system was to be looked for in a proper combination of both. But the amount and kind of physical exercise which was proper for one child might be either excessive for another or inadequate for a third, and only by medical inspection could physical exercise be adapted to the needs of each child. One of the most difficult, and yet one of the most important, questions of school hygiene was how to combine educational work with physical training, so that both should be productive of benefit and not of injury to the child. Proper alternation of mental and physical exercise was one means of preventing this, but attention must also be paid to the nature of the physical exercise. The movements of drill at the word of command and the performance of new and unaccustomed muscular actions involved considerable mental, as well as bodily, fatigue, and must not be looked upon as relaxation. Marching or dancing to music after the steps had already been learned, and regular play, such as games of ball, tended, on the contrary, to remove mental fatigue and to develop the body. Shooting with rifles properly adapted to their size and strength was an exercise which tended to bring out many of the best qualities of boys. If boys were trained to shoot, many of them would, he thought, when they left school join the ranks of the Volunteers instead of becoming hooligans. The increased exercise which physical training entailed necessitated more food and the question of how best to feed children in school without interfering with parental responsibility was one which, they trusted, might be elucidated at the Congress. But all attempts to develop a healthy race would be ineffectual if they took care only of the children who were at school now. They must look a generation ahead and consider that the children who were at school now 15 or 20 years hence would be the fathers and mothers of a fresh set of school children. It was, therefore, of the utmost importance that boys and girls should be instructed in the laws of health, the need of cleanliness, the dangers of impure food or water, and the evils of alcoholic abuse. Such instruction should not be given by lectures, which were likely to be misunderstood or forgotten, but by actual demonstration. The assembly of so many experts from all parts of the world would almost certainly enable the Congress to give an authoritative opinion upon the most important questions of school hygiene, so authoritative that it could hardly be disregarded either by corporations in towns or by governments of countries. It was true that the proper carrying out of a system of school hygiene would involve expenditure, yet this would be amply repaid in the greater health and greater working power of the community. Sir Lauder Brunton concluded his speech by referring to the great loss that the cause of school hygiene had sustained in the deaths of Professor Hermann Cohen, who lectured at the first International Congress at Nuremberg, and of Dr. Paul Schubert, who was the honorary general secretary of that Congress; he recounted some of the work that these two men had done on behalf of the health of the children.

Votes of thanks to Sir Lauder Brunton and Lord Crewe brought the meeting to a close. A telegram was despatched to the King expressing its grateful thanks for his interest, to which Sir Lauder Brunton subsequently received a reply.

A Bird's eye View of the Work in the Sections.

In the section on the Physiology and Psychology of Educational Methods and Work Dr. T. S. CLOUSTON (Edinburgh) read a paper on the Hygiene of Mind in Education. He considered that hygiene was a means to strengthen the defences of the body and that teachers should know the correlation of mind and body and education should be regarded as mental hygienics. Professor TAAV LAITINEN (Helsingfors) described the Methods of Temperance Teaching in Finland and said that quite lately the Government had advised instruction in the laws of temperance as part of a child's general education. Dr. DAVID SOMMERVILLE (London) communicated a paper on Education in Hygiene for Teachers, in which he

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, *accompanied by* a remittance.

Answers are now received at this Office, *by special* arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in *reply to Advertisements*; copies only should be *forwarded*.

Cheque and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them *and all other Advertising Agents.*

Agent for the Advertisement Department in France.—J. ASTIER 31, Rue Bapts, Asnières, Paris.

by the public health authority of New York. Convalescent children should be sent to the country apart from the question of infection, but because they were weak. He agreed that the assistance of teachers was most necessary; they alone could detect when a child was getting weak and teachers should be trained so as to second the efforts of the school medical inspector. All these services would necessitate a considerable increase to the medical staff under the medical officers of health.

Dr. T. H. C. STEVENSON (London) read a paper on Scarlet Fever Prevalence among School Children in London. He had calculated that by the time children reached the age of 14 years 14·5 per cent. had suffered from scarlet fever, and there were also unrecognised cases. This was a small figure considering that in a place like London all must be occasionally exposed to the risk of infection. He thought the primary case infected others in a day or two. Statistics proved that there were fewer secondary cases where there had been prompt removal of the first patient. A case that passed unobserved had, he calculated, sixty times more opportunity for spreading the disease than one which was at once detected and removed. The great difficulty was in regard to the unrecognised cases.

Dr. HENRY ZAHOR (Prague, Bohemia) read a paper showing that from the age of five to ten years there had been a great increase of cases of chicken-pox and scarlet fever in the primary schools of Prague. The prevalence of diphtheria had decreased in consequence of the general use of anti-diphtheritic serum. Measles was very prevalent and spread rapidly at the commencement of the school year. This was due to the indolence of the parents who let children go to school while in an infectious condition. Though measles, scarlet fever, and chicken-pox were now more and more prevalent the proportion of fatal cases had decreased. Small-pox simply did not exist at all and typhoid fever had decreased in consequence of improved drainage. He concluded by urging that there must be compulsory notification and isolation and that all "contacts" must be carefully examined and watched. In regard to tuberculosis, he found a great increase in the number of cases from five to ten years of age.

The CHAIRMAN now declared the meeting open to a general discussion on the papers that had been read.

Dr. J. O. SYMES related that in the neighbourhood of Bristol the attempt during an epidemic to swab the throats of all persons exposed to any risk and to submit the result to bacteriological examination led to such an outlay as very soon to stop the practice. The bacteriologist received *2s. 6d.* per swab. At Manchester those who collected the swab also got *2s. 6d.* each. *2s. 6d. per family*, it was urged, should suffice and there was a danger of preventing proper precautions by exaggerated expense. It should suffice to examine only really suspicious cases. But it was difficult to tell at once, and *suspicious* cases had been sent to the hospital where they contracted the true disease. He did not think the report "*short variety*" of diphtheria bacillus sufficient evidence of a real case.

Dr. P. BOOBBYER, medical officer of health of Nottingham, said he had only 250 cases of diphtheria per 100,000 of the population. Certain districts suffered less, but he did not think that this was due to any form of immunity. Certainly he had a very poor district where there were but few cases. He thought that the swabbing of throats was very useful. Thus, as an instance, among 1000 children there had occurred 20 cases of diphtheria. He then had all the 1000 children examined and the result was that of the swabs taken from them ten contained the bacillus. The ten children were at once removed and the spread of diphtheria was there and then stopped. Again, at the Nottingham General Hospital diphtheria attacked patients and the staff. He therefore had swabs applied to every throat of both patients and attendants. As a consequence 34 persons were found to be affected and had to be removed, but the epidemic at the hospital was stopped at once.

Dr. A. K. CHALMERS, medical officer of health of Glasgow, said that all practitioners were invited to send swabs, if possible, of all persons in a tenement house where a case of diphtheria had occurred. If there was any immunity in very poor districts it was because there was more sanitary surveillance exercised in such quarters. At Glasgow the practitioners did not make any charge for sending swabs to be tested.

Dr. WILLIAM BUTLER (Willesden) said that he had two poor districts, a new and an old district, and it was the new district which suffered most from diphtheria. He found that under the pretext of ventilating sewers, sewer airs were discharged under bedroom windows, and he thought that there was a relation between sewer airs and the prevalence of diphtheria. He concluded that clinical evidence was as necessary as bacteriological evidence and that negative evidence was not conclusive. There might be the bacillus in the throat of a person apparently in good health and none in the case of a person who was obviously ill.

Dr. F. J. POYNTON (London) summarised a paper which he presented on ill-health and school attendance. He urged that much more attention should be given to cases of rheumatism. These were often neglected or attributed to growing pains. They led to weakening of the heart and, unless the child had the necessary rest, to irremediable heart disease. There were cases of brain rheumatism or chorea that were put down to naughtiness or idleness. Many children not naturally robust became pale, languid, irritable and highly nervous. No actual disease was discovered. With the rich such children were sent to some bracing health resort. With the poor they remained at school to develop serious constitutional diseases.—Dr. J. JOHNSTONE WEIR (Jarrow) applauded the above paper, insisting that it could not be too loudly proclaimed that there was no such thing as growing pains: it was rheumatism.—Dr. BOOBBYER, Dr. S. DAVIES (Woolwich), and other speakers all agreed as to the great need of more careful watch over cases of rheumatism, and then Dr. NIVEN replied, and insisted that old districts had bacilli of a low type of virulence which immunised the populations without producing virulent cases.

Looking Back.

THE LANCET, *SATURDAY*, August 8th, 1829.

FOREIGN DEPARTMENT.

NEW METHOD OF ARRESTING HÆMORRHAGE.[1]

AT the meeting of the Académie Royale de Médecine, on the 16th of July, M. Amussat communicated the details of his new method of arresting hæmorrhage from large blood-vessels without the aid of ligature, compression, or any other expedient hitherto employed. His plan is originally founded on the common observation, that lacerated and contused wounds are but seldom attended with hæmorrhage, which M. Amussat conceived, could not be accounted for but by some peculiar change, both of form and vital properties, which the vessels undergo in such lesions. He accordingly began a series of experiments, in which he tried to obtain the same results, and eventually found that the laceration, contusion, &c., of large vessels, in most cases, produces only a momentary suspension of the hæmorrhage, but that it is permanently arrested by a methodical *contortion* of the bleeding vein or artery. According to his experiments, he proposed the following plan:—the vessel being seized with a small pair of forceps, the branches of which are firmly fixed by a strong screw, is extracted, so as to be denuded for about five or six lines, and after having been isolated as much as possible from the surrounding *cellular tissue*, is held between the fore finger and thumb of the left hand, whilst the forceps are twisted five or six times, according to the size of the vessel, until the portion between the teeth of the forceps is lacerated; the artery then spontaneously retracts, and is distinctly seen and felt to pulsate, though the hæmorrhage is completely arrested. On close examination of the vessel, it appears that the internal coat, being divided in the same manner as by a ligature, contracts and forms a sort of ring (*bourrelet*), by which the further exit of blood is obviated. It is of great importance to fix the extremity of the vessel between the fingers of the left hand, or else the contortion will be found to extend through the cellular tissue, as far as the next collateral branch.

[1] Only the first paragraph has been transcribed.

infections when these have passed beyond the reach of antiseptic applications. Of the other methods the more important are the application of hot fomentations, the evacuation and drainage of abscess cavities, massage, the methods of Bier and Klapp, and the various forms of radiotherapy. In all of these methods—and it is this which has induced me to bring them together here under a single heading—we have, as a prime factor, a determination of lymph from the circulating blood to the focus of infection; and, as a secondary factor, a conveyance into the circulating blood of a lymph which has in passing through the focus of infection impregnated itself with bacterial products.

I shall, before I have done, explain to you, in connexion with the passage of blood fluids into the focus of infection, that these blood fluids will exert in every case some antibacterial effect upon the invading bacteria; and, in connexion with the passage of bacterial products from the focus of infection into the circulation, that these products will effect very important modifications in the blood both in the direction of reducing and in the direction of increasing its antibacterial power. There are thus *a priori* grounds for expecting useful therapeutic effects from each and all of these methods. It is in your knowledge that such useful therapeutic effects are every day achieved. There are, however, also, as you will already have appreciated, *a priori* grounds for expecting that there will occasionally result from the application of these methods not only failure but disaster. It is familiar matter to you that these methods are often ineffective. You know also that disaster has followed massage, the venous congestion of Bier, and radiotherapy. It will presently become clear that disaster may on *a priori* grounds be expected wherever, by the application of these methods, bacterial products are introduced into the blood in immoderate quantities.

4. SERUM-THERAPY.

All the therapeutic methods which have been in question above have application only to localised bacterial invasions. Serum-therapy has more ambitious aims. After a successful application in connexion with the treatment of diphtheria this method has—and this without intermediary trial in connexion with simple, localised, and correspondingly more tractable forms of infection—been applied to the treatment of the most desperate and complicated varieties of bacterial infection. Serum-therapy has, as you know, found application not only in connexion with septicæmic infections but also in those most complex mixed infections which we have to deal with in pulmonary phthisis. In these applications serum-therapy has, I submit, everywhere disappointed expectation.

It is not enough to realise the fact of failure. Wherever, in connexion with the application of any therapeutic method, we meet with repeated failure we are called upon to make a critical regress upon the facts and inquire into the rationale of our method. We are, in accordance with this principle, here required to consider whether there is any assured basis for the treatment of bacterial infections by serum-therapy.

Serum-therapy is, in point of fact, built upon the postulate that the animal organism possesses the capacity of responding to the incorporation of practically unlimited quanta of bacterial cultures by a practically unlimited output of antibacterial substances. Now this assumption, while it might be thought to win support from the analogy of the effective immunising response which occurs where diphtheria or tetanus toxin is incorporated into horses, is, as I hope presently to show you, entirely out of accord with the results which are ordinarily obtained by the inoculation of bacterial cultures. When you shall have considered how different are the ordinary everyday events which supervene upon bacterial inoculations from that miracle of immunisation which accomplishes itself when diphtheria toxin is administered to a horse, you will, I believe, be quite prepared to recognise that we have no justification for the assumption that there will result from the introduction of a moderate quantum of serum into a patient's blood anything in the nature of a marked increase of his antibacterial power.

5. EXPECTANT TREATMENT.

I now come to the expectant method of treating bacterial disease, the last of the five therapeutic methods which were enumerated at the outset of this paper. We have, as you appreciate, in the expectant treatment a therapeutic method which is based upon the adoption of a policy of non-intervention as between the invaded organism and the invading bacteria: a therapeutic method which commits the destiny of the patient—so far as that destiny is involved in the issue of his conflict with the invading microbes—entirely into the hands of chance.

We are all agreed that by this method, which consists essentially in feeding and nursing the patient and keeping him at rest in bed, far better results are achieved in generalised bacterial infections than any that could be obtained by active medication. We need only to call to mind here the fact that from 80 to 90 per cent. of recoveries are under the expectant treatment achieved in typhoid fever.

There is, however, also a reverse to the medal. We have in the case of typhoid fever from 10 to 20 per cent. of fatal cases. We have in streptococcal septicæmias and in plague—to mention only two out of the more formidable bacterial infections—a mortality in comparison with which the percentage of recoveries is quite insignificant. Further, we have in Malta fever a considerable percentage of cases in which the fever drags out almost indefinitely.

This indictment of failure—of failure in connexion with septicæmic diseases—is very far from being the only indictment which can be brought against the expectant treatment. Let me ask you to realise that generalised bacterial infections are, comparatively speaking, rare and transient incidents in life. The really serious ills of life are the various localised bacterial infections which sooner or later fasten upon every man, never afterwards releasing their hold. It follows from this that a graver allegation is brought against the general value of a method of treating bacterial disease when it is alleged that such method has no application in connexion with localised bacterial processes, than when it is pointed out, as it has been here in connexion with the expectant treatment, that it is a method which utterly disappoints in many varieties of generalised infection.

Now the graver charge of having no application in connexion with localised bacterial diseases may be brought against the expectant method of treatment. It is only, if I rightly apprehend the matter, in the case where life is threatened by the entrance of bacteria or bacterial products into the blood—and, as we shall see later, not even invariably in that case—that nature addresses herself in a serious manner to the task of immunisation. As long as a bacterial invasion is still strictly localised nature seems to oppose to it nothing more than a passive resistance. It follows that it is idle in connexion with localised infections to wait upon nature and to expect from her any work of immunisation. I am wont to insist that the statistics of the expectant method of treatment in the case of localised bacterial infections are hardly more favourable than those of the Pool of Bethesda. You will remember, in connexion with that Pool, that an angel was wont to come down and trouble the waters *once* in seven years, and that, after that event, the man who stepped down *first* into those waters was cured. You will, I believe, not fail to see how the facts are mirrored to us in this comparison if you will take any series of cases of endometritis, middle-ear disease, chronic bronchitis, lupus, or let it be any other localised bacterial disease, and will elicit in connexion with each case the term of years during which the infection has persisted. I myself can call to mind, from among the patients I have under treatment, no fewer than three who have suffered from lupus each for a period of over 40 years.

PRINCIPLES OF THE METHOD OF VACCINE-THERAPY AND SKETCH OF THE MACHINERY OF IMMUNISATION.

Having now passed in review with you the therapeutic methods which are in use in the treatment of bacterial disease, I propose to turn to the main theme of my discourse and to deal with the treatment of bacterial disease by vaccine-therapy. The essential feature of this method is the scientific exploitation for therapeutic uses of the protective machinery with which the organism is equipped. We shall do well here to turn our attention for a moment to a study of that machinery.

There are two elements which come into consideration in connexion with the protection of the organism against invading micro-organisms—the leucocytes with their digestive ferments constitute one of these elements; the antibacterial substances in the blood fluids constitute the other. A word or two will be appropriate in connexion with each of these elements of our protective machinery.

(a) *Leucocytes.*—The leucocytes come into consideration in connexion with resistance to bacterial infection by virtue on retired pay (dated August 7th, 1907). Major S. Macdonald has been appointed to Hong-Kong.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major Thomas McC. Foley to be Surgeon-Lieutenant-Colonel (dated July 20th, 1907).

A DISTINGUISHED NAVAL MEDICAL OFFICER.

Inspector-General James Porter, R.N., C.B., who presided over the Navy, Army, and Ambulance Section at the Exeter meeting of the British Medical Association, joined the medical department of the navy in 1877, was surgeon of H.M.S. *Orontes* during the Egyptian war, 1882 (Egyptian Medal, Khedive's Bronze Star); served on shore with the Royal Marine Battalion defending Suakin from May, 1884, till the actions at Hasheen, March 20th, 1885; attack on Sir J. McNeil's zareba, Tulufik, March 22nd; the attack on the square of Guards and Marines, March 24th; and at the taking and burning of Tamaai, April 3rd (Suakin, 1885, To Frek clasps). He landed from H.M.S. *Doris* during the Boer war, 1899, 1900, and was in medical charge between Oct. 20th, 1899, and Oct. 12th, 1900, of the naval forces employed on shore: (1) in defence of Stormberg; (2) in Lord Methuen's advance from Belmont to Magersfontein; (3) in Lord Roberts's advance from Enslin to Belfast, *viâ* Klip Drift, Paardeberg, Pretoria, &c.; (4) with General French's column from Belfast to Barberton, *viâ* Carolina; medal with eight clasps, inscribed "Belmont, Modder River, Relief of Kimberley, Paardeberg, Driefontein, Johannesburg, Diamond Hill, Belfast"; present at Graspan (with the assault); Magersfontein, Poplar Grove, capture of Pretoria; twice mentioned in despatches; promoted to Deputy Inspector of Hospitals Oct. 21st, 1900, for above services; C.B. June 26th, 1902; as Deputy Inspector was in charge of naval medical establishments at Chatham and Gibraltar. Promoted to Inspector-General, his numerous friends and the service generally were pleased to note that he has been recently selected as Inspector-General of Haslar, one of the largest general hospitals in the world, to which the Naval Medical School and training of the sick berth staff are attached.

Correspondence.

"Audi alteram partem."

THE ACOUSTIC LIMITATIONS OF THE BINAURAL STETHOSCOPE.

To the Editors of THE LANCET.

SIRS,—With reference to your interesting account from the *New York Medical Journal* of "the acoustic limitations of the binaural stethoscope" I should like again, as I have often done in the clinical wards, to draw attention to the inadequateness of the double (flexible) stethoscope in the appreciation of aortic shock sounds, impulses, and of cardiac force. Shock sounds and impulses quite impalpable can be appreciated by the unaided ear, and better through the medium of the rigid stethoscope, that would be entirely missed with the flexible instrument, and I have known cases of sacculated aneurysm thus to escape diagnosis. I have also frequently observed the binaural auscultator to mistake conducted oral breath sounds for morbid pulmonary sounds. It would be easy for a mischievous expert to play tricks with a binaural auscultator which he could not do with one who had an ear disengaged for the appreciation of extrinsic sounds. Undoubtedly the binaural or flexible stethoscope has many conveniences and some advantages, and direct auscultation is neither cleanly nor always decent; the important matter is for each physician to depend upon the instrument whether rigid or flexible to which he is most accustomed in order that he may preserve that sense of comparison upon which so much depends in auscultation; but everyone should also possess and use on occasion the rigid stethoscope for the reasons above specified amongst others.

I am, Sirs, yours faithfully,

Wimpole-street, August 3rd, 1907. R. DOUGLAS POWELL.

EARLY NOTIFICATION OF BIRTHS.

To the Editors of THE LANCET.

SIRS,—I have been surprised to notice that there seems to be a certain amount of hostility to a measure which has been brought before Parliament for the purpose of making a first step towards lessening the present needlessly high infantile mortality rate. This measure is the Early Notification of Births Bill introduced by Lord Robert Cecil, Mr. Sherwell, the Right Hon. A. Lyttelton, and others. It will probably be known to most of your readers what the purport of this Bill is, but its whole effect may be summed up in a sentence. The Bill provides for the notification to the health authority of a borough or district of every birth within 36 hours of its occurrence, such notice to be given by the father if resident in the house at the time or, failing him, by any person in attendance on the mother. As amended in committee of the House of Commons this is made an adoptive measure applicable only at the request of a local authority and subject to the local authority satisfying the Local Government Board that they are able to administer the measure in a satisfactory manner. There is no fee payable on either side. It may, perhaps, be interesting to note here that in France, where the registration has to be made within 72 hours, the father has to appear in person before the official and make a declaration in the presence of two witnesses and, moreover, pays a fee of 2 fr. 50 c. for the privilege.

I learn with surprise that this measure has aroused the protest of certain members of the medical profession because of the possible inclusion of the members of the profession under the head of "person in attendance." It is exceedingly probable that the clause could not possibly apply to the profession in more than 30 per cent. of births, seeing that this is the outside percentage where a medical man is present. But even of this 30 per cent. it is not likely that the father would be freed from the liability to notify in more than a very small number of cases, so that the risk of the medical man being liable to notify as the "person in attendance" is really whittled down to an almost infinitesimal risk: probably not in more than 1 per cent. of the total number of births would any obligation fall upon the medical man. For a very small risk it seems that the profession wishes to block the progress of this beneficial measure. The early notification of births seems obviously the first step towards combating infantile mortality. Every authority on the subject is absolutely agreed upon this point. If you are to try to save the lives of infants it is necessary to know that they are in being. It is the first thing that the practical administrator of public health finds that he needs. It has been asserted that early notification is a fad. Nothing could possibly be further from the truth. It is the first necessary step and all the really practical men are unanimous in favour of it; no faddist has ever come near it except to hint at dislike of anything so intensely practical.

For a layman and for a practical administrator of public health, such as I claim to be, it is quite impossible to understand what objection can possibly be taken to this measure by anyone. Whom does it injure or threaten to injure? Whose work does it interfere with or take away? Whose emoluments does it affect? Whose status or dignity does it infringe upon? The only people that I can conceive of thinking that they are affected at all would be those connected with the Registrar-General's department; but the heads of that department are in most complete sympathy with the Bill and its objects. But that medical men should object to such a measure seems to me a contradiction, an outrage upon the nature of things, and I cannot even come at a beginning of the clue to the objection to it. Yet it is the opposition of a medical man, representing the opinion of medical men, that has blocked this Bill and endangers its passing. I have no hesitation in saying quite bluntly that on the passing or not passing of this Bill depend the life and health of scores of little helpless babies. They are very small and helpless, but after all it is murder to kill them, and merely to let them die is not free from some blame. I know that we have saved life and promoted health in Huddersfield by our efforts, and the key of the whole position is the early notification of births to the health office.

I yield to no one in my profound respect and admiration for the medical profession. I owe my own life and health to its skill and care. It is the proudest of my possessions that I was akin to Sir William Broadbent, so that it is in no vaccines obtained from broth cultures; and vaccines obtained by the trituration of bacteria, by autolysis, or treatment by caustic alkalies and subsequent precipitation with acids, as substitutes for vaccines which have been sterilised in the ordinary way by heat.

It has been claimed in connexion with each of the modifications here in question that its employment is dictated both by weighty *a priori* considerations and analogies and by the event of actual experiments. Of the *a priori* considerations and analogies which have been adduced I will consider only the contention that living vaccines ought to be preferred to vaccines which have been sterilised by heat on the ground that inoculations with the former furnish close analogies with actual infections which are known to confer immunity, whereas there are no such close analogies between these last and inoculations with vaccines which have been subjected to the action of heat. To this I could rejoin that even supposing the temperature of boiling water, which the objector has here in view, to produce in a bacterial culture chemical changes as fundamental as those produced by that temperature in egg-albumin, a temperature which just suffices for sterilisation might quite well leave the chemical constitution of a bacterial culture for all practical purposes unaltered, just as there is a temperature, short of the coagulating temperature, which will, when applied to a hen's egg, prevent germination, leaving the chemical characters of its albuminous substances substantially unaltered.

If I refrain from all attempt to meet with analogical reasonings of this kind the many other suggestions which have been put forward in connexion with the constitution of bacterial vaccines, it is because I hold that in scientific controversy the proper procedure is always either to bring proof of a contested proposition, or to make *tabula rasa* by demonstrating that such proof is not forthcoming.

Now analogical reasonings cannot supply proof; nor can they, seeing that no argument from analogy can ever be effectively discredited by the production of any conflicting analogy, restore to us that *tabula rasa* which is ever, next after assured knowledge, the most excellent intellectual possession.

Quite other are our '*returns of profit*' where we proceed by the pathway of reasoning from experiment. By this path we arrive always at some intellectual good. Where we find a contested conclusion to rest upon a firm basis of experiment, we are entitled to incorporate it in a definitive manner into our corpus of knowledge. Where we find a flaw in the chain of reasoning we are entitled to reject and put far from us the conclusion as we do so—recovering for future exploitation unencumbered foundations.

Allow me, in view of these general considerations, to turn to the experimental evidence, and let me try to show you that the reasoning which has been held to establish that a vaccine of a particular composition is more effective than a vaccine of somewhat other composition has in every case been inconclusive.

Let us begin by realising that where an animal which has been inoculated with a particular vaccine succumbs to a test inoculation this result does not establish the conclusion that the vaccine which was employed is ineffective. It establishes only, either that the vaccine was ineffective; or, that the dosage was ill chosen; or that the test inoculation was ill-timed; or that the test inoculation was excessive; or that two or more of these factors were at fault. *A fortiori*, where comparative experiments are undertaken upon two animals or upon two different sets of animals with different vaccines, and where one of these survives while the other succumbs to the test inoculation all that has been established is that the one vaccine employed in a particular dose x has at the date of the test inoculation conferred a greater measure of protection than another vaccine employed in another dose y. Now it is obvious that unless we have assurance that the doses x and y which have been employed in the comparative experiments represent the optimum doses of these vaccines (or doses which stand in each case in the same relation to those optimum doses) we can have no assurance that the survival or non-survival of our animals is determined by the difference in the vaccine and not by a difference in the dose. Now no serious attempt has ever been made to employ in comparative experiments exactly equivalent doses of competing vaccines.

There has thus, in the course of our study of the question as to how far the particular composition of the vaccine is material to the success of an inoculation process, come to light the fact that we are not yet in a position to affirm that one variety of vaccine possesses an advantage over another from the point of view of its power of conferring immunity. It has also become clear that no progress can be made in the resolution of this ulterior question until we have settled the preliminary questions as to how the equivalent doses of two vaccines can be arrived at, and as to how the immunising efficacy of a bacterial inoculation can be most effectively tested. So material are a comprehension and a resolution of these issues to the understanding of the principles of vaccine-therapy that I need not make any apology for embarking upon their consideration.

What is the Best Method of Measuring the Immunising Effect produced by the Inoculation of a Bacterial Vaccine?

The method of test inoculation—i.e., the method of inoculating a living culture into an animal which has been previously treated with a vaccine and of comparing the result obtained in this animal with the result obtained on a control animal inoculated with a similar test dose of living culture—has hitherto been accepted as a perfectly satisfactory method of gauging the immunising effect of a vaccine. While it is undeniable that this method supplies in the case where the vaccinated animal survives and the control animal succumbs a satisfactory proof of the immunising power of the vaccine, it may in the case where the vaccinated animal succumbs deceive us in deepest consequence. Where the test inoculation has been undertaken with an excessive quantum of the living culture we may fail to register the acquirement of a quite considerable measure of protection. Again, when the test inoculation follows hard upon the inoculation of the vaccine the animal may, and we shall presently see the explanation of this, succumb as rapidly as, or even before, the control animal without any fault being attributable to the vaccine. In fact, the more rapid death of the vaccinated animal after a premature test inoculation may, paradoxical as this may at first sight appear, be in reality indicative of the potency, instead of the impotence, of the vaccine.

It is clear, if these things are so, that there may quite well be a more excellent method of gauging the immunising effect of a vaccine than that which is furnished by judging by the event of a test inoculation. Reflection will show that if we can take it as assured—and I submit that we can—that the machinery of immunisation is, at any rate in its broad features, understood, and if it is indubitable—as in point of fact it is—that the phagocytic reaction of the leucocytes and the content of the blood in antibacterial substances can be measured with a degree of accuracy which is sufficient for all practical purposes, and if by means of these quantitative methods it is feasible to construct curves showing the march of events and the changes which are associated with the inoculation of a bacterial vaccine, it must be possible by the aid of such curves to gauge in a more accurate manner than by any test inoculation the immunising effect of a vaccine, and to determine in the case of any two vaccines what are the doses which produce precisely equivalent effects. The method of vaccine-therapy which is here in question proceeds upon these assumptions. It postulates that we have in the curves which set forth changes in the bacteriotropic power of a patient's blood, and in particular in the curves which set forth changes in the opsonic index of his blood, a record of blood changes which exert in every case a dominating influence upon that patient's bacterial infection. I am, let me assure you, very sensible of the fact that justification for these generalisations can be afforded to you only by the gradual accumulation of evidence. Allow me, however, pending the time when such evidence shall have accumulated in your hands, to forestall events and to endeavour to call up before you by the aid of this immunisation chart a picture of the facts which were elicited by my fellow worker Captain S. R. Douglas, I.M.S., and myself in connexion with a case of localised staphylococcus infection which was successfully treated by the inoculation of staphylococcus vaccine.

Increased Phagocytic Response is Associated with Successful Immunisation, and this Increased Phagocytic Response is Dependent upon an Increase in the Opsonic Power of the Blood Fluids and not upon an Increased Capacity for Spontaneous Phagocytosis on the Part of the White Corpuscles.

The immunisation chart which I here display will furnish to you a typical illustration of the achievement of increased commend this passage to the very careful study of all who employ such figures, for in truth it is too often forgotten that statistics form a science with unalterable rules and limitations; too often are the most intricate problems treated by medical men in the same light and heedless manner as is, let us say, the "fiscal question" settled in a few dogmatic pronouncements by the Briton who rejoices in his sound common-sense but is blissfully oblivious of the existence of a science of political economy that can have any bearing on so simple a matter.

Dr. Hale White made appreciative reference to the study of statistics as the latest of the bevy of auxiliary sciences that medicine has summoned to her aid, and he could hardly have adduced a better instance of the application of accurate knowledge to medicine than the employment of those advanced mathematical methods which Professor Karl Pearson and other distinguished mathematicians have placed at her disposal: the biometrical method would seem to offer a more promising weapon to attack the mysteries of heredity than any that clinical medicine has yet brought forward.

I am, Sir, yours faithfully,

August 5th, 1907. [illegible]

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

To the Editors of THE LANCET.

SIRS,—I have a small grumble to make. Nothing could be better than the production of the Journal of the Royal Army Medical Corps. To the bibliopegist magazines as a rule leave much to be desired, but here he meets with a near approach to absolute perfection. The admirably printed pages lie open of their own accord; no need to bend back or even to flatten out, and yet they are firmly fixed and the roughest use leaves them undetached. Nor are the contents unworthy of their setting. It is true that leading articles and editorials seldom or never appear, but every communication has a *raison d'être*; the author has something to say and says, or is made to say, it with becoming brevity. Padding is rarely perceptible—a remarkable thing in a journal of close upon 150 pages. The contributors are all officers of the corps and their contributions, which emanate from all parts of the world, are full of information and interest. Until their journal came to life they had difficulty in recording their observations in a permanent form and many valuable statements and comments have no doubt been lost to science. As an incentive to professional zeal the journal of the Royal Army Medical Corps most effectively supplies a long-felt want. Amidst all this excellence there is, however, one defect: the price of a copy is 2s. net. The organisers must, of course, be allowed to know their own business best, but these are the days of cheapness and large circulations can only be secured by small prices. To secure a *clientèle* among the civilian practitioners of the empire, should this be desired, the charge must be reduced.

I am, Sirs, yours faithfully,

August 3rd, 1907. G.

*** The excellence of production noticed by our correspondent of course regulates the high price.—ED. L.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The Leeds and West Riding Medico-Chirurgical Society.

FROM the annual report of this society, which has been recently circulated amongst its members and which was adopted at the annual meeting held in May, it appears that the work has been carried on in the same way as in recent years. During the session 11 meetings—eight ordinary, one pathological, and two clinical—have been held and the average attendance of members was [illegible]. The society now numbers [illegible] members, [illegible] ordinary members having joined during the session of 1906-07. The meetings of the society are held on certain Friday evenings from October to May and as its members come from all parts of the West Riding and, indeed, from beyond its limits, these meetings are much valued not only for their scientific importance but as a means of medical men meeting and keeping up friendships and acquaintances which otherwise might fall into abeyance. The library of the society and that of the medical faculty of the University are amalgamated and under the direction of one honorary librarian who represents both bodies. The library and reading-room, which are in the buildings of the medical school adjoining the Infirmary, where the meetings are held, are open to all members of the society, and the librarian is authorised under an arrangement to forward books to country members.

The West Riding Rivers Board and Disposal of Leeds Sewage.

On March 2nd of this year it was mentioned in this column that in consequence of the poll of citizens being unfavourable to the undertaking of the scheme of the city council for the purchase of 1000 acres of land on the Temple Newsam estate for the purposes of sewage disposal, the West Riding Rivers Board had decided to take legal proceedings against the corporation under Section 7 of its Act. The case came on at the Assizes before Mr. Justice Grantham. On behalf of the corporation Mr. E. Tindal Atkinson, K.C., admitted the offence but explained the great difficulties the city had had to contend with. Ultimately, after a consultation between counsel, a form of order was submitted to his lordship with the approval of both parties. Mr. Justice Grantham then made the order from which we take the following paragraphs:—

> And it is ordered that the defendants do abstain from the further commission of the said offence, but that this part of the order be suspended for 12 months.
>
> And it is further ordered that the defendants do forthwith commence and diligently proceed to carry out the necessary works to enable them to treat and deal with the whole of the dry-weather flow of liquid sewage matter falling or flowing or being carried into the River Aire through the sewers and sewage disposal works of the defendants situate at Knostrop, and after the said works have been completed to treat and deal with the whole of the said dry-weather flow, so that the suspended solids in the effluent of the dry-weather flow discharged into the river shall not at any time thereafter, except from unavoidable causes, exceed [illegible] parts in every [illegible] parts. Provided that after the said works have been completed no penalties shall be incurred by the defendants in respect of any pollution until three samples of the effluent of the dry-weather flow have been obtained on three different days, each of which shows the suspended solids to be in excess of the proportions hereinbefore mentioned.
>
> And that the defendants do apply to Parliament and use their best endeavours to obtain in the next ensuing session of Parliament an Act to empower them to acquire all necessary lands and carry out and complete all necessary works for the efficient purification of all sewage matter falling, or flowing, or being carried into the said River Aire, or to prevent it from so falling, or flowing, or being carried as aforesaid.

New Professorships at the University.

Following on the resignation of Professor Miall, who has been responsible for the teaching of biology in Leeds almost since the initiation of the Yorkshire College in Leeds upwards of 30 years ago, the council of the University decided to institute two new professorships, one of zoology and the other of botany. To the professorship of zoology the council has appointed Dr. Walter Garstang. Professor Garstang is an M.A. and D.Sc. of Oxford and has been lecturer and examiner in his own university. He has lately filled the position of chief naturalist to the Marine Biological Association. Dr. Blackman, who is a graduate of Cambridge and for some time a Fellow of St. John's, has been appointed Professor of Botany. He has done a considerable amount of work on fungi.

August 9th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Dr. James Finlayson Memorial Lecture.

At a meeting of friends of the late Dr. James Finlayson held shortly after his death in the hall of the Faculty of Physicians and Surgeons, Glasgow, it was resolved to commemorate his life, professional services, and learning by the institution of a lectureship. The committee has invited Dr. Norman Moore of St. Bartholomew's Hospital to be its first lecturer and he has undertaken to give the lecture probably about the beginning of next February. The exact date and subject of the lecture will be announced in due course. The subscription list which was opened in order to obtain money to found the lectureship is not yet closed.

Appointment to the Western Infirmary, Glasgow.

At a meeting of the board of managers held last week Dr. John M. Munro Kerr was appointed physician for diseases of be but little the better for *anything else.*" More than two centuries have passed since this most suggestive essay of Locke appeared and yet nothing has ever been written which brings out more clearly what should be the aim of physical education in our schools than the words which I have just quoted, written by the man who may fairly be described as the founder of school hygiene in England. At the present time, while the greatest interest is being taken in every department of education, it is a noteworthy and remarkable fact that people are coming to see that there is a very close association between education and the health of the people, that the axiom that there cannot be a healthy *state in this world* without health of body and mind was never *more true than* in the existing condition of society; in other words, it is at last beginning to dawn upon the public that it is absolutely essential that medical science must be more and more associated with the machinery of teaching. This most important principle—*that is, the close relationship* between medical science and the instruction of the young—has a very direct bearing upon both teacher and taught.

INFLUENCE OF MEDICAL SCIENCE ON TEACHER AND PUPIL.

At the present time in the world's history we are no longer content that a teacher of the youth of a nation should be *one who simply hears lessons in a catechetical way* and who guides his pupils in the ordinary routine of school studies; we *expect* that those who *instruct* children should have themselves passed through a training school or college where they have learned not merely the theory of education *in all its branches* but have acquired a knowledge of the common principles of bodily health and also of the methods of placing *this information* before children, and have been *taught to observe* and recognise those physical defects and *mental weaknesses in their* pupils which may require special care and *attention. We also consider that our teachers* should have a knowledge of the various systems of physical culture and be able to show some prowess in games, while *from* the point of view of the pupil modern opinion demands that the health of the children should in no way suffer while at school—nay, more, that the children should be instructed while there in the fundamental laws of elementary hygiene which, if acted upon, will help to make them useful and healthy citizens of the State. Indeed, one of the most remarkable tendencies of our modern education is the desire to make the school not only of use but a real pleasure in training boys and girls more and more in the practical side of life, in developing initiative, and in fostering self-reliance, and especially in *instructing* them in the direction of how to keep healthy.

Now, if we look at what has been taking place of late in the most advanced nations of the world we shall be struck with the fact that ideas as to the relationship of the public schools to medical science have gone through a most interesting process of evolution. The first step in this developmental movement was taken with the object of preventing schools becoming centres of infectious or contagious disease, then followed the effort to supply to the children while in school a hygienic environment, that is, school-rooms properly seated, lighted, heated, and ventilated, and with no overcrowding. This in turn was succeeded by a *demand for medical* inspection of children, both on their entrance to the *schools* and during their subsequent school career in order to ascertain whether they were fit to go to school—that is, in a word, whether their physical condition was compatible with their being benefited by the instruction which they will require, and, if so, whether their sojourn in school was causing or increasing certain diseases, such as curvature of the spine, rickets, tuberculosis, anæmia, &c., and whether their apparent *dulness*, short-sightedness, deafness, or *headaches*, *might* not depend on preventable causes (eye, ear, and *throat*). Another great advantage of *medical* examination of school children would be that it *would* afford opportunities to obtain accurate scientific *records* of the measurements of the physical development of the body, in regard to such points as height, weight, chest capacity, and the like. We would thus arrive at approximate anthropometric standards and be able to *observe* if children *were normal* for their age, and also to ascertain *in the case* of the undersized whether their *undeveloped* condition was, from the associated history, probably due to hereditary or prenatal causes or to faulty rearing, improper nourishing, bad housing, *unhealthy* environment, or malnutrition. In this way *facts* would soon be collected which would have an important bearing on the question of physical racial degeneration. The *latest* stage in this evolutionary process in school life is the effort that is now being made to promote the physical health and *development* of the child.

PHYSICAL EDUCATION IN SCHOOLS.

Now this condition of vigour and good health, *so* far as the school is *concerned (for the teacher can do little* to settle that most *serious coexisting public problem*—the influence of the home environment), *may be brought about*, or rather an attempt may be made to solve the *question*, by various *means*.

1. The children while at school should be taught, both by example and by precept, the simplest rules of how to live, the necessity for fresh air and for pure water, and for healthy homes, and the relative nutritive value of the various kinds of food which are ordinarily used. They should be instructed *in the* simple and ordinary laws of health and temperance and in the importance of such matters of personal hygiene *as cleanliness, the care of the skin*, including the hair and *nails and of the* mouth and teeth (not more than 3 per cent. *of all children of school age* have sound teeth), how to deal *with sudden emergencies*, and *how much can* be done to prevent the onset and *spread* of infectious disease. There is no doubt that in schools with gymnasia personal hygiene can be *best taught as it* can be *practically demonstrated* there; that attention to the care of the body brings about that most desirable condition which is called "*feeling fit.*" Girls should be taught the elements of *cooking* at school by practical lessons as well as the principles of housekeeping; and seeing that we now compel them to attend school, and in this way deprive *them to a large extent* of that home experience and personal contact with infants which was more *the rule formerly, it is surely* incumbent to see that they are taught *those elementary truths as to* the care of infants *that* all *girls from ten to 13 years* of age might know. I am fully convinced that the time has arrived when, if we *are to* put a stop to those conditions which bring about physical degeneration, especially in our large towns, and if we are to solve fully many pressing public health problems, *such* as the terrible wastage of infant life, as well as the survival of numbers of them with a poor physique and a weak constitution, and the preventable deaths caused by consumption, children in the primary schools should be instructed in hygiene and temperance. In order that this shall be *carried out properly* facilities should be afforded to the *teachers for special* training in these subjects, and finally, *hygiene* and temperance should be not only included in the curriculum of studies, but they should be reported upon by the inspectors of the schools. I trust that as a result of what will be brought before us at this great Congress by experts from all parts of the world England will, in the language of the Prince of Wales, "wake up" to her duty *towards* her school children.

2. The children should be made to do exercises both in the school and in the *adjacent* gymnasium, if *there* is one attached to *the school. Nothing is more* valuable *for* children who *so often are kept for long periods* in a cramped position than what are called the deep breathing exercises (which *stimulate* the circulation through the internal organs) *combined* with those movements which bring into play the muscles which move the spine backwards. When such exercises are engaged in by the pupils for a period varying from three to five minutes at the end of each *hour, or even* at the termination of every two hours in the schoolrooms (the *windows* of which should be open), *they* are of enormous value *in* quickening the *circulation*, in using up *more* oxygen, and in counteracting the deleterious effects of the school-desk and of a too long rest in one position or *attitude*.

3. Lastly, the children must be instructed *in physical* education and have time for games and athletic *exercises*. We want our children to be so trained *physically that each* faculty of the body may be *fully developed, and this* can be done (*a*) by those methods *employed* in Swedish schools, which consist *mainly of movements* without the use of any apparatus or musical accompaniment, which *tend to develop* groups of correlated muscles; (*b*) by gymnastic *exercises* and musical drill at the schools, and *dancing in the case of* girls; (*c*) by games in the *open air, either in school* playgrounds (and no school should be now constructed without them) or in athletic *fields*; and (*d*) by swimming when baths are available. *In cities where there* are public baths these might be utilised, *and I am pleased to say that in my own*

July 2nd, M. Didsbury said that the treatment of nail biting was a source of difficulty. Instead of protecting the nail, as has hitherto been the practice, he thought that it was better to prevent complete closing of the teeth (*desarmer la dent en relevant l'articulation*). He showed an appliance which served this purpose; it fitted the lower molars and was fastened behind the front teeth. Other methods consisted in the use of a gold cap fixed to one molar tooth, a false tooth purposely made too long, or an apparatus removeable at meal times which seemed to be the best of all.

Scarlet Fever in Paris.

Scarlet fever is prevalent in Paris just now and has been increasing in severity for the last four months. Statistics show that there is an average of more than 500 cases a week. The special hospitals, the hospital at Aubervilliers, and Bastions 27 and 29 are crowded with patients. More accommodation has been provided by transferring the patients in the Hôpital Bichat to other hospitals, principally Lariboisière and Beaujon, and using the Hôpital Bichat for scarlet fever cases. Fortunately, there are now some signs that the epidemic is decreasing.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Experiments on Cancer.

Professor Bier of Berlin, writing to the *Deutsche Medizinische Wochenschrift*, reports the details of an investigation into the influence of the injection of blood of animals on inoperable growths in the human subject. He finds that the injection of 10 or 20 cubic centimetres of pig's blood made under aseptic precautions into healthy human tissue produces a local reaction which reaches its climax within three days and then gradually disappears. Pyrexia also occurs, and when the injection is repeated a smaller quantity of blood is sufficient to produce the same effect owing to the hæmolytic action induced in the individual. Lamb's blood has a milder action but no harm was done by the injection of pig's blood. The injection of the defibrinated blood of a creature belonging to a different genus is certainly the safest way of producing inflammation and fever. This alien blood has no dissolving influence on normal tissue but only on cancer. Pig's blood injected into cancerous tissue caused a diminution of the secretion; the growth itself was in some cases not influenced, while other growths became rapidly necrosed and reduced in size, so that Professor Bier believed them to have nearly healed, but on microscopical examination this opinion proved erroneous. In one case of cancer in a lupus scar treated by four injections of pig's blood the growth disappeared and even on microscopical examination no cancerous tissue was found; the patient had, however, previously undergone treatment by the Roentgen rays so that no case has undoubtedly been cured by injections of alien blood. Two cases of extensive inoperable cancer of the cheek and of the cervical glands are described in detail where injections were made, the result being that in one of them there was total necrosis and in the other a formation of connective tissue within and round the cancer developed. Professor Bier has concluded that there is no very obvious prospect of malignant growths being successfully treated in this way.

August 6th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Science in Session.

THE Italian Association for the Advancement of Science after two "false starts" in 1839 and 1875—the first at Pisa, the second at Palermo—has this time got fairly under way, and if long, laborious, and well-inspired preparation can insure success may look forward to a series of triumphs little, if at all, inferior to those of the British Association, whose work it aspires to emulate and on whose lines it is organised. Its first meeting will be held at Parma from Sept. 23rd to the 29th, and its programme will include original papers on the more recent developments of inductive research. The medical sciences will be strongly represented, particularly in anatomy, human and comparative; while embryology will have the attention it is so worthily entitled to at the hands of the distinguished professor of that subject in the University of Pisa, Dr. Guglielmo Romiti. Unusual attraction is held out by the Tenth Section, that of anthropology, ethnography, and palæo-ethnology, the last-named science being represented by Professor Luigi Pigorini of the University of Rome, where he holds the chair of Palæontology. It is right to remember that in Parma were initiated and carried to a high pitch of development those studies on the "Terramare," of which the results are so richly *en évidence* in the local museum—a collection, indeed, which has few equals in its presentation of the industrial products found in the most antique "stazioni" of the pure age of bronze. In Parma, moreover, at the eastern extremity of the city there exists one of the most noteworthy "Terramare"—among the very few in which at the greatest depth there survive the various orders of "palafitte" (piles) in the most perfect preservation. Expressly for the palæo-ethnologists who may intervene on the occasion there will be opened a trench reaching down to the virgin soil so as to furnish an object lesson in the Italian "Terramare" hitherto withheld from science. The programme of Section X. as a whole will be one of the most interesting of the number—thanks to the the zeal of its accomplished President, Professor Pigorini aforesaid. Another theme on which the association may be expected to throw much light is the connexion between "Foreste, Idrologia, Igiene" (forest-growth, rainfall, and hygiene). THE LANCET has often referred to the importance of re-afforesting the denuded hill-sides and uplands of Italy if only to minimise the autumnal and vernal floods, with the disasters they bring to every local interest, sanitary as well as agricultural and commercial. Signor Vittoria Perona, professor of "Economia Forestale" at Italy's one school of forestry (Vallombrosa), has recently given to the world a vivid picture of the widespread misery consequent in Latin countries on systematic tree-felling unbalanced by equally systematic tree-planting, taking as his text the words of Humboldt: "By destroying the forest growth which covers the mountain side mankind in all climates prepares for generations unborn two great calamities—a lack of timber and a deficiency of water." A perusal of Professor Perona's pages will form an apt preparation for the discussion which is expected on their all-important theme—a discussion which, it is hoped, will not be without practical results in legislation general and local.

The Second International Congress on Physio-Therapy.

As already announced in THE LANCET, this Congress, to which the hygienic interest of so many countries is eagerly looking forward, will meet in Rome from Oct. 12th to 17th under the presidency of the Senator Guido Baccelli, the veteran head of the Roman Medical School. From the list now before me of the names of those who are expected to intervene some notion may be formed of the importance attached to its proceedings—the English-speaking world being represented by some of its leaders in medicine, surgery, and hygiene. The same may be said of other nationalities—France, Germany, Austria, Denmark, Sweden, Norway, Belgium, Holland, and Switzerland; while the Far East will have not a few delegates, prominent among them being those from Japan. I may again draw attention to the very liberal conditions of transit by land and sea provided by the Government with a view to enabling the "Congressisti" of non-Italian nationality to visit the many climatic and balneary resorts throughout the kingdom, the development and equipment of which have evoked so much enterprise and outlay on the mainland and in the islands. The *Libretto di Viaggio*, available for ladies equally with the male sex, will entitle its possessor to travel at reduced fares from Oct. 1st to Nov. 15th to every place of medical interest in the kingdom—at a season, moreover, when Italian weather contrasts favourably with that of most other countries, the British Isles not excepted!

August 6th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Vienna Serum Institute.

THE new premises of the Vienna Serum Institute have been recently opened and the horses, altogether 47 in number, have been transferred to their new stables. The institute serves two distinct purposes. In the first place it is devoted high arch. The lower jaw is feeble and of an infantile type, the ramus forming an acute angle with the body.

Trunk.—External occipital protuberance to tip of coccyx, 510 millimetres. Well-marked lordosis with slight dorsal scoliosis, convexity to the right. No obvious beading of ribs; seven costal cartilages articulate with the sternum on each side, the seventh pair at the junction of the mesosternum with the metasternum. The sternum is abnormal. The manubrio-sternal junction is opposite the articulation of the third pair of costal cartilages, there is no episternal notch. The three parts of the sternum measure 55, 64, and 19 millimetres respectively = 138 millimetres.

Limbs.—Arms and legs are well nourished and fairly muscular and not disproportionate in size. The humerus measures 213 millimetres, the ulna 201 millimetres, the femur 340 millimetres, and the tibia 295 millimetres. There is slight genu valgum on the left side. The terminal phalanges of the fingers and toes are rudimentary.

My colleague, Mr. E. J. M. Phillips, dental surgeon to the Royal Infirmary, reports on the teeth; the boy at the age of 16 years should have lost all the deciduous teeth and should possess 28 permanent teeth. Six temporary teeth are still present, and only 15 of the permanent set have erupted. The structure also of the teeth is poor; only three of the permanent teeth are sound.

isolated as a distinct type by Pierre Marie and Sainton[3] in May, 1897, under the title of cleido-cranial dysostosis. The leading features are (1) aplasia more or less marked of the clavicles; (2) exaggerated development of the transverse diameter of the cranium; (3) delay in the ossification of the fontanelles; and (4) hereditary transmission. 1. The aplasia of the clavicles is well marked in this boy and, as most commonly seen, is bilateral. (A radiograph by Mr. C. Thurstan Holland showed a complete absence of any bony tissue.) 2 and 3. The head is typical, except that the palatal arch is not very high. As regards the fourth point, the heredity in my case does not fall into line. The mother, though short, is well formed and has normal clavicles; the boy's younger brothers, aged 14, 12, and 7 years respectively, and a sister, aged 10 years, have all well-formed clavicles. The father is a tall, well-formed man.

It is interesting to note that in achondroplasic dwarfs the clavicles and the bones of the cranium are not affected, and this has led M. Apert[4] to associate achondroplasia and cleido-cranial dysostosis as two variations, opposed and complementary, the first characterised by an insufficiency of the cartilaginous ossification, the second by an insufficiency of the membranous ossification. The origin of the clavicle in membrane is not generally admitted, however suggestive M. Apert's hypothesis may be. Gegenbaur has shown that the clavicle is a membrane bone like the cranium and may be connected with it by supraclavicular bones (sturgeon), or even arise directly from it (teleostei), and that in the acrania the clavicles are wanting. Bruch asserts that the clavicle is a membrane bone in man, but Gegenbaur holds it to be a mixed and Kölliker a cartilaginous bone. However this may be, Apert considers both conditions to be hereditary dystrophies the result neither of an accident of uterine development nor of fœtal disease, but in reality "definite and hereditary variations of the human type, specific and sudden, well recognised by zootechnists, which the Neo-Darwinian school term, with de Vries, mutations." Couvelaire considers that the causal element, whatever it may be, does not

FIG. 1. FIG. 2. FIG. 3.

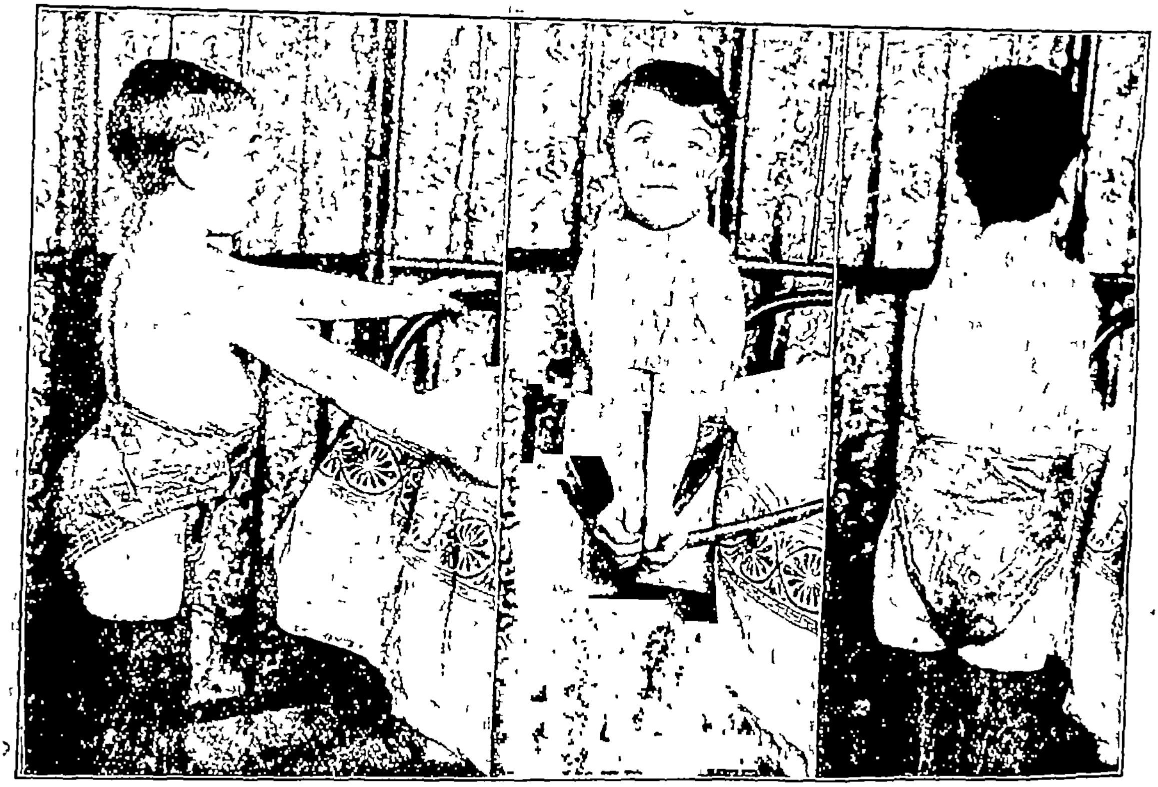

Fig. 1 shows the lordosis. In Fig. 2 the absence of the clavicles is well demonstrated. Fig. 3 shows slight dorsal scoliosis with convexity to the right. These figures all show abnormal mobility of the shoulder joints.

The lad is 16 years old. His height is four feet and half an inch, and his weight 4 stones 8 pounds (average height for age, five feet four and a half inches; weight, 8 stones 7 pounds). He has chubby, rosy cheeks. His gait is waddling (coxa vara). The genitals are puerile; there is some scanty hair on the pubes. On superficial examination one would not be struck by the absence of the clavicles—the shoulders are held well back and the chest is well rounded. I think Mr. J. Lewis Owen of Holyhead, who sent me the case, is to be congratulated on his acuteness in detecting the malformation. Finally, the boy is intelligent. He reached the fourth standard at school, and was a great favourite in the ward for his helpful ways. The reproductions of photographs illustrate well his appearance and the abnormal movements possible at the shoulder-joints. One shows the lad standing on his hands, and I might add that he can pull himself up chin high at the full stretch of his arms.

Dwarfs seem to fall into two marked groups, first those of perfectly proportionate but diminutive formation and, second, those due to mal development or disease. My case belongs to the second group; he is an example of the class of case of stricken humanity in China and has died as truly a martyr in the cause which he had at heart as if he had been stricken down by the hand of violence. For years past he had been unwell, but, notwithstanding this, he came to England a short while ago for further hospital training, the better to fit him to carry on his work in China. Returning to Hankow, though still in ill-health, he died practically in harness. His death is deeply deplored both by his friends in England and by those among whom he laboured for so long. He was an ex-President of the Medical Missionary Association of China and also a member of the Ophthalmological Society. He leaves a widow and one daughter to mourn him and to them we tender sincere sympathy in their bereavement.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Hoyer, formerly professor of physiology and histology in the University of Warsaw.—Dr. Albrecht, late head of the Technical Department of the Odontological Institute of the Berlin University.—Dr. Albert Weiss of Cassel, who, in addition to various medical works, published many poems, both original and translations from the Bohemian.—Dr. Alex. Geh, professor of dermatology and venereal diseases in the University of Kazan.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the First Professional Examination of the Conjoint Examining Board held on July 16th, 17th, 18th, and 19th, the following gentlemen were approved in the subjects indicated:—

Chemistry and Physics.—George Aldridge, St. Bartholomew's Hospital; Thomas Stevens Allen, Guy's Hospital; Charles Kelson Atlee, St. Mary's Hospital; Samuel Isaac Blairmann, Middlesex Hospital; Charles Grinling Bunn, Charing Cross Hospital; Terence Campbell Butler, Westminster and King's College Hospitals; Thomas Clarke, Leeds University; Cyril James Weston Clayton, St. Mary's Hospital; Claude Gray Colyer, Birkbeck Institute; David Henry Davies, University College, Cardiff; Bartholomew Gidley Derry, University College, Bristol; Alfred George Timbrell Fisher, University College, Bristol; Frederick Thomas Fisher, Birmingham University; Hubert Gibson, Liverpool University; Herbert Marshall Gilbertson, St. Bartholomew's Hospital; Arthur Oliver Gray, Birkbeck Institute; Kenneth Banks Greenwood, London Hospital; William Edward Halliman, Charing Cross Hospital; Mohammad Zaky Hanafy, Guy's Hospital; Ernest Ravensworth Hart, Guy's Hospital; John Roll Hayman, Middlesex Hospital; Edward Howard Heaton, London Hospital; John Eric Hepper, St. Bartholomew's Hospital; Henry Sydney Colchester Hooper, London Hospital; Frederick Malcolm Stirling Hulke, Middlesex Hospital; Darrell Robert Norman O'Neale Humphrey-Davy, St. Mary's Hospital; Arthur Edward Huxtable, Charing Cross Hospital; Cornelius Kennedy, Liverpool University; Geoffrey William King, Guy's Hospital; Adolph Bertie Kramer, Edinburgh University; Allan Wellesley Lewis, St. Mary's Hospital; Charles Cooper Ling, London Hospital; Arthur Lowndes, Manchester University; Reginald Hutchinson Lucas, Guy's Hospital; William Henry Matthews, Liverpool University; William Frank Morgan, London Hospital; Owen Colville Morphy, Birkbeck Institute; George Marshall Oakden, Sheffield University; John Francis O'Malley, Middlesex Hospital; Frederic John Palmer, St. Mary's Hospital; George Hugh Piercy, University College, Bristol; John Pinder, Leeds University; Oswald Pitt, Manchester University; Alfred Graham Poock, Cambridge University; Richard Frith Quinton, London Hospital; John Magnus Redding, Charing Cross Hospital; Cecil Goodwin Reinhardt, Leeds University; John Richard Cook Stephens, London Hospital; Edward Algernon Weaver, Birmingham University; John Douglas Webb, Liverpool University; Cyril Guy Whorlow, St. Paul's School; Miles Astman Knight Wood, St. Bartholomew's Hospital; and William Worger, University College, Bristol.

Chemistry.—Burgess Barnett, St. Bartholomew's Hospital; Allan Stanley Coalbank, St. Bartholomew's Hospital; John Baptist Gregory Dotto, St. Bartholomew's Hospital; Geoffrey Garland, Leeds University; Arthur Ernest Williams Idris, University College; Walter Louis Ingram, Guy's Hospital; William Fidler Mason, Leeds University; Eugene Andrew Joseph Murphy, King's College; John Hayward Paget, Charing Cross Hospital; William Piper, Manchester University; Marcus Holroyd Ratton, Guy's Hospital; John Basil Robertson, London Hospital; Edmund Uniacke Russell, King's College; Arthur Tilbury, Guy's Hospital; and Ramanathan Vamadeva, King's College.

Physics.—Ahmed Abdel-Al, Guy's Hospital; Frank Cunninghame Cowtan, St. Thomas's Hospital; Arthur Lewis Davies, University College; Maurice Dwyer, Leeds University; Alexander Bentoul Esler, St. Thomas's Hospital; Maberly Squire Esler, St. Thomas's Hospital; Alexander Percival Green, Polytechnic Institute; Arthur Holmes, Liverpool University; Samuel Hutchinson, University College; George Basil Henley Jones, Guy's Hospital; Harold Bishop Logan, University College, Bristol; Eadbert Ralph Longstaff, St. Bartholomew's Hospital; Hamed Mahmud, St. Thomas's Hospital; Courtenay Henry Gerald Pochin, Guy's Hospital; Ellis Herbert Sydney Scarr, Manchester University; Cecil Hearle Symons, Charing Cross Hospital; and Ivan Lindley Waddell, St. Bartholomew's Hospital.

Elementary Biology.—Thomas Stevens Allen, Guy's Hospital; Wilfrid Andrew, King's College; Horace Arthur Arkill, Charing Cross Hospital; Herbert Ferris Barge, Birkbeck Institute; Basil Fraser Beatson, Leys School, Cambridge; Jamshedji Sorabji Bhajiwalla, Bombay University; Philip Norman Button, Middlesex Hospital; Frederick William Campbell, University College, Cardiff; Nai Cheune, London Hospital; Andrew Cory, London Hospital; Arthur Lewis Davies, University College; Edward Percy Drabble, London Hospital; John Herbert Drinkall, Middlesex Hospital; Alexander Bentoul Esler, St. Thomas's Hospital; Richard Shirley Fawssett, St. Bartholomew's Hospital; Philip Cuthbert Collingwood Fenwick, St. Thomas's Hospital; Frederick Thomas Fisher, Birmingham University; Hubert Gibson, Liverpool University; Herbert Marshall Gilbertson, St. Bartholomew's Hospital; Arthur Oliver Gray, Birkbeck Institute; Ernest Ravensworth Hart, Guy's Hospital; Arthur Edward Huxtable, Charing Cross Hospital; William Sadler Hyde, Guy's Hospital; Adolph Bertie Kramer, Edinburgh University; Charles Cooper Ling, London Hospital; Adolph Richard Niell MacGillycuddy, University College; William Henry Matthews, Liverpool University; Henry Marie Alphonse Menage, St. Bartholomew's Hospital; William Frank Morgan, London Hospital; Joseph Morrey, Manchester University; Cyril Scotter Owen, Manchester University; Charles Henry Greville Penny, Guy's Hospital; Michael Gladstone Pettigrew, Sheffield University; John Magnus Redding, Charing Cross Hospital; Walter Graham Reynolds, St. Mary's Hospital; Stanley Alfred Riddett, Middlesex Hospital; Guy Frederick Romer and William Edward Tanner, Birkbeck Institute; John William Thomas, Leeds University; Claude William Treherne, St. Thomas's Hospital; Arthur Geoffrey Turner, St. Bartholomew's Hospital; Ivan Lindley Waddell, St. Bartholomew's Hospital; Edward Algernon Weaver, Birmingham University; and Cyril Guy Whorlow, St. Paul's School.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the preliminary science examination for the Licence in Dental Surgery the following gentlemen were approved in the subjects indicated:—

Chemistry and Physics.—Cecil Hastings Bradnam, Guy's Hospital; Herbert Brown, Holt School of Science, Birkenhead; Alfred Fisher Camp, University College, Reading; Frederick Scott Cooper, Leeds University; Frederick James Craig, Charing Cross Hospital; Frederick Graham Emanuel, Polytechnic Institute; Bernard John Geekie, Oxford University; Max David Gillis, München University; Gerald John Harborow, Birkbeck College; Gilbert Henry Hickman, Guy's Hospital; George Hobbs, Science and Art Institute, Walsall; Edward Palmer Hudson, Birkbeck College; Eric Greaves Ireland, Liverpool University; Leslie Gordon Kinnersley, University College, Bristol; Harold William Knowling, Harris Institute, Preston; Stanley Lawson, Brighton Municipal Technical College; Leonard Clive Matthews, Birmingham University; Harold Mawson, Bradford Technical College; John Dudley Melhuish, University College, Bristol; Victor Mayfield Morris, Felsted School; Hubert Walter George Randell, Birkbeck College; Warren Longtoft Roberts, Leeds University; Gordon Evelyn Rowstron, Birkbeck College; Charles Frederic Leyson Ruck, Guy's Hospital; Irvine Rushton, Municipal Technical School, Halifax; Bernard Edward Patrick Sayers, Birkbeck College; Leslie Shovelton, Science and Art Institute, Walsall; Patrick Barry Stoner, Technical School, Brighton; William Suffield, Technical College, Sunderland; Robert Douglas Breen Turner, Liverpool University; William Hector Wotton, Birkbeck College; and George Trevor Yonge, Dulwich College and Birkbeck Institute.

Chemistry.—Eric Horsfall Chesters, Birmingham University; Charles Repton Faulkner, Birmingham University; George Theodore Douglas Hughes, Municipal Technical School, Liverpool; William Caffyn Miller, Polytechnic Institute; Cecil Graves Morris, Guy's Hospital; William Henry Whitworth, Royal Technical Institute, Salford; and James Wignall, Harris Institute, Preston.

Physics.—Ernest Walker Bacon, Alleyn's School, Dulwich; Albert Bangert, Polytechnic Institute; Harold Barrett, Birkbeck College; Arnold John Chapman, Birkbeck College; Sydney Ingram Fillingham, Manchester University; Frederic Edwin Gill, Liverpool University; Edward Aubrey Clement Knox-Davies, University College, Reading, and Reading School; Cyril Arthur Pollard, Birkbeck College; Vincent Joseph Powell, Liverpool University; Frederick Gordon Pulford, Birkbeck College; Grantley Smith, University College, Bristol; Clifford Tonlson Watson, High School, Middlesbrough; and Gordon Stafford Woodhouse, Birkbeck College.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the examinations of the Scottish Conjoint Board held in Glasgow in July the following candidates passed their respective examinations:—

First Examination (five years' course).—Francis William Grant (with distinction), Glasgow; James Grant Morrin, Glasgow; Morris William Rees (with distinction), Festiniog, North Wales; Francis Patrick Quirk, New South Wales; James Douglas Wright, Coatbridge; William Millerick, Castlemartyr, County Cork; and John Boyd Michie, Alloa.

Second Examination (five years' course).—Surendra Kumar Sen (with distinction), Bengal; Edith Hufton, Madras; Robert John Helsby (with distinction), Denbigh, North Wales; and Harold Hope Scott, Banbridge. *Four years' course:* Thomas Mitchell Jamieson, Belfast.

Third Examination (five years' course).—Richard B. M. Sullivan, Belfast; Ormonde Ensleigh Belcher, Liverpool; Thomas Sholto opposite (right) side show infiltration with rapidly growing columns of carcinoma cells but the tube is free from growth. A papillomatous growth on the surface is malignant—no corpora lutea are seen.

I have to thank Dr. R. Sanderson, senior surgeon to the hospital, for kindly permitting me to make use of the case.

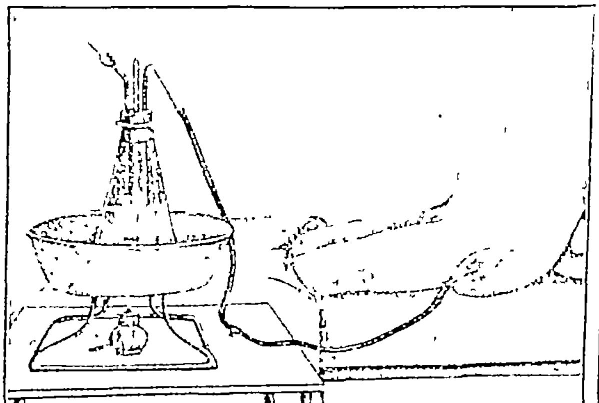
Brighton.

ON THE CONTINUOUS ADMINISTRATION OF FLUIDS BY THE RECTUM IN THE TREATMENT OF ACUTE GENERAL PERITONITIS.

By B. G. A. MOYNIHAN, M.B., M.S. Lond., F.R.C.S. Eng.,
SURGEON TO THE LEEDS INFIRMARY.

In the *Annals of Surgery*, 1906, Vol. XLIII., p. 231, Dr. Le Conte of Philadelphia, in discussing the treatment of diffuse septic peritonitis, drew attention to the method of introducing large quantities of fluid into the rectum which he had witnessed in the clinic of Dr. J. B. Murphy at Chicago. The results which Dr. Murphy and Dr. Le Conte had attained in the treatment of acute peritonitis due to appendicitis were so remarkable that I hastened to put the principles enunciated in that paper into practice. Certainly the most novel and in my judgment the most important of the several points mentioned therein had reference to the continuous administration of fluid by the rectum after operation. I have come to the conclusion, after a fairly large experience of it, that there are few recent therapeutic measures which are in value equal to this. I have up to the present time treated 19 consecutive cases of acute general peritonitis due to appendicitis with two deaths, and the recovery of several of these patients is, I believe, largely, if not solely, due to the continuous administration by the rectum of saline solution over a period of two to four days after the operation. But it is not only in such cases that I have found this method of value. In two recent cases of partial gastrectomy and in one case of complete gastrectomy the recovery of the patients was undoubtedly helped by this abundant supply of liquid to them. I propose to describe briefly the method of administration which I have found the most useful and shortly to add the details of a few cases in which I have adopted it.

The first point is concerned with the selection of a proper rectal tube. To find a perfectly satisfactory one is no easy matter. The patient during the administration of the infusion is generally propped up in bed, and if a short solid tube is used the rubber tube attached to it is apt to kink. I have used in all my recent cases a tube one foot in length and half an inch in diameter, made of pewter, with a slightly bulbous extremity which is introduced into the rectum. The tubes are supplied to me by Messrs. Allen and Hanburys. At the end and on all sides of this bulb holes are pierced so that fluid can easily pass through them and flatus can escape and can be seen bubbling through the supply-tank or funnel. If a single aperture only is present in the tube it is apt to be blocked by fæces. When there are many openings the rectum is equally distended above the sphincter and the obstruction of the flow of fluid by fæces does not occur. The tube is introduced about from two to three inches into the rectum, and at the anus it is bent sharply so as to lie easily on the bed. To its outer end a long rubber tube is attached, which leads to the source of supply at the bedside. The most convenient vessel to hold the saline solution is an "infusion flask" (Sahli's pattern). This is of the type of a Florence flask, but instead of being globular it is triangular in shape, having a large base. The flask holds from three to four pints and is closed at its neck by a rubber stopper, through which there are three openings; the one admits a glass-tube, which at one end reaches to the bottom of the flask and at the other is attached to the rubber-tube leading to the rectum; a second admits a thermometer; and a third a tube which acts as an inlet for air. The whole glass flask is immersed in a bath of hot water, beneath which a spirit lamp burns. This secures an equable temperature of the saline solution. The best temperature is from 100° to 102° F. If the fluid is hotter than this it is not retained well; its temperature is probably three or four degrees lower than that shown by the thermometer when the rectum is reached. When the tube has been introduced into the rectum and the flask attached the latter should be elevated so that its base is about from three to six inches higher than the rectum. The saline begins to flow and continues to flow at the rate of about a pint an hour. It is not desirable to introduce more than one and a half pints, or at the most two pints, during the first hour; subsequently a rate of one pint in the hour should be maintained. The rapidity of the flow is altering by raising or lowering the flask. It should be regulated by the patient's comfort. If a feeling of tightness or distress is caused the flow is too rapid. As a rule no uneasiness is caused till about five pints have been introduced. It may then be necessary to retard the flow for half an hour or an hour, or even to stop it for a few minutes. In only one case has less than five pints caused distress. If the rate of flow be regulated properly and the temperature of the fluid not altered from seven to ten pints can be introduced without any interruption. If flatus reaches the rectum it can escape by the tube. If, as rarely happens, the fluid introduced acts as an enema the tube may be replaced as soon as the bowels have acted. Care and almost constant attention on the part of the nurse are necessary to make the administration a success; a marked difference in the capacity of nurses will probably be discovered by all who try the method. In place of the infusion flask a funnel may be used which the nurse must keep filling from a jug. This is tedious and a variation in the temperature of the fluid is inevitable.



Apparatus for the continuous administration of fluids by the rectum.

The largest quantity of fluid taken by any patient of mine during the first 24 hours was 16 pints; the largest quantity administered was 29 pints, extending over three days. These quantities were borne quite easily, without any distress whatever. The change in the appearance of a patient who is absorbing fluid so rapidly is very remarkable. If the case is one of acute general peritonitis the patient who looks livid, whose eyes are sunken, whose skin is moist and cold, whose mouth is so parched that his tongue can hardly move, begins in a few hours to look ruddy and "clean," his mouth is moist, his eyes are bright, and all his aspect is one of comfort and contentment. The pulse gains volume and improves steadily in character, urine is passed in large quantities, and the skin keeps moist. Not a few patients say that they feel very hot and some of them perspire freely. It is a question, perhaps, as to how far one is justified in carrying this treatment in patients whose kidneys are defective. In the case of partial gastrectomy to be mentioned presently I gave 16 pints of saline solution in 24 hours; this represents a large dose of sodium chloride. At the end of the 24 hours it was noticed that the patient's face looked fuller and rosier than it had ever done and a slight œdema of the lower eyelids developed. The injection was therefore discontinued for 12 hours to be again administered without any ill effect.

The chief use and the most remarkable achievements of this method are certainly in the treatment of acute general peritonitis, but I have found great help from it in the preparation and after-treatment of certain cases of gastric disease. Patients who suffer from pyloric obstruction in a marked degree are often wasted and shrivelled and parched. Such patients stand operation badly if the obstruction is

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Medical Inspection of School Children.

ONE of the Standing Committees of the House of Commons on Tuesday considered the Education (Administrative Provisions) Bill. Amongst the clauses which the committee agreed to retain in the measure was Clause 10, which relates to the medical inspection of elementary school children. There was a good deal of discussion on some of its details. Mr. LUPTON, for example, moved an amendment that the medical inspection should only be made of those children whose parents expressly wished it, but this proposal was defeated. Mr. MCKENNA, the Minister for education, however, pointed out that parents who objected to the medical inspection of their children would have power to withdraw them from it. The clause emerged from the Committee with little amendment.

HOUSE OF LORDS.

THURSDAY, AUGUST 1ST.

Vaccination (Scotland) Bill.

Lord HAMILTON of DALZELL moved the second reading of the Vaccination (Scotland) Bill. The noble Lord (who at times was indistinctly heard in the press gallery) explained that the object of the Bill was to introduce into Scotland the provisions of the English Vaccination Act of 1898 as regarded conscientious objection, and also to extend to Scotland the principles of the English Vaccination Bill of this year, which allowed a statutory declaration of objection to vaccination to be made before a justice of the peace or a commissioner for oaths. He thought that it was a self-evident proposition that the English legislation of 1898 with respect to vaccination should be extended to Scotland. The number of people who objected to compulsory vaccination might not in Scotland be relatively so great as in England. Their grievance was just as great and their claim for redress as strong. He thought that noble lords must recognise that grievance. In spite of the almost illegal leniency with which parish councils had been permitted to administer the law with regard to vaccination the number of prosecutions had steadily increased during the past ten years, and last year the number of them was 64. He trusted that their lordships would give the Bill a second reading.

Lord BALFOUR of BURLEIGH moved the rejection of the Bill. He said that there was no foundation for the suggestion that there was any analogy between the circumstances of Scotland and England, and there was no case for the adoption of the Bill so far as the circumstances of Scotland were concerned. The Government had passed the English Vaccination Act of 1898 because the circumstances which existed at that time made it necessary and judicious. There had been an enormous amount of discontent with the law with regard to compulsory vaccination in England. Local authorities were in revolt and the due administration of the law could not be secured. Therefore, with the consent of both Houses of Parliament, compulsory vaccination for England had been abandoned. There had never been anything analogous to these circumstances in Scotland. A great deal of the evil that had grown up in England was attributable to the fact that a child had to be vaccinated within a much shorter period than was the case in Scotland, though he believed that the period had been lengthened by recent legislation. In Scotland, if after six months a child was not vaccinated, the registrar communicated with the parish council and the parent was then offered to have sent to him a public vaccinator who would vaccinate the child, and if that offer was refused the parent was prosecuted. Up to the time he left the Scottish Office they had for a series of years vaccinated successfully 97 per cent. of the children who lived six months after birth, and in the remaining 3 per cent. were included those who were not susceptible to vaccination and those that had been lost sight of. For his part he had not seen the slightest discontent with regard to law as it existed in Scotland, and he believed that it had the active support of the public. The whole thing was moving with perfect smoothness, although he agreed that a distinction should be made between those who were honest objectors and those who were merely careless or negligent. He had every respect for those who did not believe in vaccination, though he did not think much of their intelligence, but he had no respect for those who said it was an interference with individual freedom. Almost every portion of government was an interference with individual freedom, and those who were most loud in their condemnation of all interference with freedom were the very people who were most anxious to interfere with the freedom of adult people to get a glass of beer or something else. Therefore, the statement that this was a wrong interference with the freedom of the subject was a statement that would not bear investigation. The true doctrine was this, that in a matter of this kind it was important for the community to have power to protect itself against one of the most infectious and loathsome of all diseases. Although he would not see anything very dreadful in fining a man half a crown or even ten shillings for breaking the law, he thought it was wrong to imprison any man for conscience' sake. During the time he was at the Scotch office there was not a single case of imprisonment for disobedience of the Scotch law regarding vaccination, though he feared that there had recently been one, as he had received from a correspondent a report about one man who had been sentenced to ten days' imprisonment for neglecting to have his child vaccinated, and he could not imagine any more regrettable circumstance or anything more calculated to strengthen the agitation against the administration of the vaccination laws. He believed, however, that there must have been some very special circumstances in this case to have led to the imprisonment. The real agitators in this matter of vaccination were not the conscientious objectors but those who desired to see the vaccination laws abolished altogether. They had not been furnished with any expert opinion on the question and therefore he said that the noble lord and his advisers were not dealing fairly with the House or the public in Scotland in this matter. He had also to complain at the delay in introducing the Bill. They were now in the month of August and the Bill had not been in the other House and they were not given any opportunity of consulting the people of Scotland to ascertain whether there was any demand for it. The procedure of the Government had been to prevent the question being tested in Scotland, and if as he hoped they would, their Lordships rejected the Bill, he thought that they would be doing a wiser thing than if they passed it. What they were asked to do by the Bill was to strike out the compulsion behind vaccination and if they took that course they would be acting wrongly.

Lord TWEEDMOUTH said that Lord Balfour's speech was a speech not in opposition to the present Bill but in advocacy of the repeal of the Act of 1898 passed by a Government of which he (Lord Balfour) was a member. So far as the information of the Scotch office went, it was that there had been very considerable representation as to the hardship of the present state of things in Scotland. He did not think that the present measure would be greatly used in Scotland but if there were really conscientious objectors they ought to have the same advantages that were given to the other inhabitants of Great Britain.

The Earl of CAMPERDOWN regretted that the Bill was not introduced in the early months of the Parliamentary session, so that the public health authorities in Scotland might have had an opportunity of expressing their opinion on it. Would the noble lord who represented the Scottish office (Lord Hamilton of Dalzell) go so far as to say that the Bill had been presented on the advice of the Local Government Board for Scotland? At the present time there did not appear to be any public demand in Scotland for the measure.

The LORD CHANCELLOR said that for his own part he had always submitted to the vaccination law on the ground of authority. The reason why the vaccination law of England was modified in 1898 was because it was desired to produce more vaccination than there had been before. The reason of this was obvious to those who looked at the circumstances. There was the perversity and obstinacy of human nature and a disposition not to submit to force common in England as it was common to all masculine races. Perhaps it was more common in Scotland than in England. The Royal Commission on Vaccination was the preparers of the English Bill and that Bill, he thought, had produced more vaccination in England. Therefore he did not think the same thing would produce harm in Scotland. The Royal Commission recommended that the change should be made in all parts of the kingdom. The Bill was, therefore, a proposal based on the recommendation of the Royal Commission. It was brought forward by the Government of the day on the statement that there was dissatisfaction in Scotland. It was calculated to advance the very purposes which Lord Balfour had at heart—the increase of vaccination. If the noble lord left people in Scotland to think that they were being differentially treated notwithstanding the recommendation of the Royal Commission he would get an irrational and unreasonable feeling against vaccination which did not exist at the present moment.

Viscount ST. ALDWYN believed that the change in the law in England had had the effect of increasing vaccination. He believed that Lord Balfour objected as strongly to imprisonment in connexion with the question of vaccination as any of their lordships. If a fine of 2s. 6d. or 10s. were a small thing, as Lord Balfour said, and Scotchmen, in spite of their traditional objection to the payment of money did not very much object to it, he still thought that their lordships should consider these fines in the light in which they might appear to the poorest in the community. Even a fine of 2s. 6d. might be felt to be a hardship to a person who knew that if he were in the same position in England he would be entitled to exemption. He was bound to say that he differed from his noble friend, and he did feel that it was impossible for him to go into the lobby with Lord Balfour against the Bill.

The motion for the rejection of the Bill was negatived without a division and the Bill was read a second time.

The Butter and Margarine Bill.

Earl CARRINGTON, in moving the second reading of this Bill, explained that it was designed to prevent fraud in the sale of butter and margarine.

The Earl of ONSLOW regretted that the Government had not seen its way in the Bill absolutely and entirely to prohibit the manufacture and sale of milk-blended butter.

The Bill was read a second time.

The Vaccination Bill.

Lord ALLENDALE in moving the second reading of the Vaccination Bill which has already passed all its stages in the House of Commons, said that the measure did not alter the law of vaccination as it stood, but simply effected an alteration in the legal method of obtaining an exemption from penalties for neglecting to have a child vaccinated. The Bill provided that no parent or custodian of a child should be liable to any penalty for the non-vaccination of the child if within four months of the child's birth he made a statutory declaration that he conscientiously objected to vaccination and delivered it to the vaccination officer of the district. He added that no serious opposition had been offered to the measure in the House of Commons.

The Bill was then read a second time.

WEDNESDAY, AUGUST 7TH.

Scottish Bills Advanced.

The Vaccination (Scotland) Bill passed through Committee.

The Public Health (Scotland) Amendment Bill was read a third time and passed.

HOUSE OF COMMONS.

WEDNESDAY, JULY 31ST.

Motor Omnibus Accidents.

Mr. TIMOTHY DAVIES asked the Secretary of State for the Home Department whether his attention had been called to the accident to a motor omnibus on Sunday last, when many people were seriously, and some dangerously, injured; was he aware that lives were daily sacrificed owing to careless driving and imperfect mechanism of the motor omnibuses which ran in the London streets; and whether he proposed to take measures to put a stop to this unnecessary sacrifice of human life and limb.—Mr. GLADSTONE answered: Inquiry is being made into the cause of this accident. I may say that the omnibus in question is reported to have been well constructed, and the driver has the reputation of being skilled and careful. The number of fatal accidents from motor omnibuses is not so great as the honourable

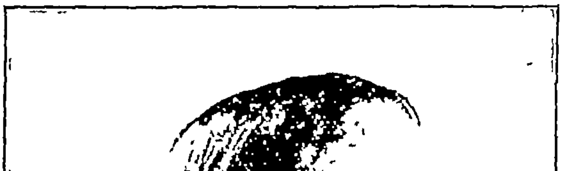
NOTE ON A CASE OF THYROID TUMOUR.

BY W. GREENWOOD SUTCLIFFE, F.R.C.S. ENG.,
CONSULTING SURGEON TO THE THANET UNION INFIRMARY;

AND

A. F. M. POWELL, M.B., C.M. EDIN.,
MEDICAL OFFICER TO THE INFIRMARY.

THE patient, aged 42 years, was stone deaf, so that a history of the duration of the tumour was not obtainable; she had been in the infirmary a few weeks only and the tumour was giving rise to distinct pressure symptoms, there being frequent attacks of dyspnœa. Removal of the tumour was decided on and carried out on March 23rd, Dr. Powell administering the anæsthetic, chloroform, and Dr. Frank Nichol of Margate assisting Mr. Sutcliffe. The usual transverse incision was made over the most prominent part of the swelling and as more room would obviously be required a longitudinal incision was added in the line of the sterno-mastoid. The bulk of the cyst at once collapsed on incision and its connexions could then be made out; it extended well under the trapezius behind, under the maxilla above, and some considerable distance into the thorax below. It was densely adherent and its separation involved a difficult and tedious dissection. Starting from behind, the bulk of the collapsed cyst was dissected up and it was found that the carotid sheath was incorporated in its posterior wall. The jugular vein was tied low down and again high up, a large piece being removed bodily with the tumour; the carotid and the vagus were easily peeled off and the upper pole of the cyst tied with a strong silk ligature. The intrathoracic portion was cut off and left *in situ* as its removal would have been attended with risk. A gauze drain was passed into the cavity and the wound sewn up with provision for free drainage in all its area. After the first day, on which the temperature rose to 103° F., the patient did well, the only trouble in healing being the sloughing of some of the skin that had been stretched by the tumour. The cyst had evidently at one time been an ordinary multilocular thyroid tumour, but the partition between the walls had broken down, making one large irregular cavity. It was in part very closely adherent to the skin which was reddened and glazed over it, entirely negativing any idea of subcutaneous anæsthesia, but when collapsed was on the whole easily separable; the hardest part to remove was the rounded semi solid upper angle, visible in the illustration as a prominence under the angle of the jaw and adherent internally to the pharyngeal muscles. At one stage of the operation there was some startling hæmorrhage from a large tributary vein low down in the neck, the arrest of which was momentarily delayed owing to temporary difficulties with respiration due no doubt to traction on the vagus, and the later stages of the operation were accompanied by a curious whistling sound from the thorax as if the pleura had been wounded, but it was probably only due to air flowing in and out of the thoracic portion of the collapsed cyst with the respiratory movements. The patient is now perfectly well and the scar is, as usual in thyroid cases, hardly visible.



Shows the appearance of the tumour before removal.

Margate.

TUBERCULOSIS AMONG SCHOOL CHILDREN.[1]

BY T. N. KELYNACK, M.D. VICT., M.R.C.P. LOND.,
HONORARY PHYSICIAN AND MEDICAL ADVISER TO THE CHILDREN'S HOME AND ORPHANAGE, HONORARY PHYSICIAN TO THE MOUNT VERNON HOSPITAL FOR CONSUMPTION AND TO THE INFANTS' HOSPITAL, HAMPSTEAD.

IT is estimated that in this country more than one-third of all deaths between 15 and 35 years of age are due to pulmonary tuberculosis. This, at least in a large proportion of cases, is the death harvest of a tuberculous seed-sowing in infancy and childhood. It is well to remember that of the 1,200,000 new lives added annually to the population of the United Kingdom, one-fourth to one-third are born into homes where conditions exist strongly predisposing to tuberculosis. The valuable work of von Behring, Calmette, and others conclusively demonstrates that much of the tuberculosis met with in adult life is dependent on infection in infancy and childhood. Tuberculosis is a disease which commonly has a long latency. The development of active tuberculous lesions is often long deferred. Statistical evidence relating to the mortality of children from tuberculosis gives no reliable expression of the amount of the disease prevailing. Tuberculosis exacts heavy toll from child life, but the penalty of death is only exceptionally exacted. Pathological returns are of much directing value. Tuberculous lesions are rarely found in the bodies of infants dying under three months of age. After this, however, there is a progressive increase in frequency. D'Espine states that in children submitted to necropsy under one year tuberculosis occurs in from 7 to 8 per cent. Taking all cases on which post-mortem examinations are made under 15 years of age, Harbitz of Christiania finds tuberculous lesions in 42·5 per cent.; Hamburger and Sluka in Vienna, 40 per cent.; and Comby in Paris, 38·5 per cent.

At present the clinical evidence regarding the amount of tuberculosis among school-going children is miserably meagre. Medical examination, so-called, is manifestly oftentimes most hastily and imperfectly carried out. For the detection of tuberculosis, especially in its latent and incipient forms, time, patience, and skill are required. Many cases of pulmonary involvement offer exceptional difficulties in the detection. Every school should be equipped with a medical officer's consulting-room. It seems to be quite unusual at present to examine children in the recumbent position and careful investigation of the abdomen is rarely undertaken. Before placing any value on returns relating to "revealed" tuberculosis in children inquiry should be made as to the nature of the diagnostic methods relied on. According to statistics at present available for England and Scotland tuberculosis is said to be present in from less than 0·5 per cent. to over 6·0 per cent. of school-going children. We have no satisfactory information as to the prevalence of tuberculosis in rural schools. The amount of active tuberculous disease in children attending London schools appears to be small; but the case of the metropolis, in this as in many other matters, stands alone and must not be taken as any indication of the state of the country generally. What is really required is not merely a numerical statement as to the amount of recognised tubercle

---

[1] Abstract of a paper presented to the Second International Congress on School Hygiene, London, 1907.

Local Government Board, however, had no power to seize the food. All it could do was to try to persuade the person who bought it not to put such stuff on the market, and this it succeeded in doing, with the result that the stuff was destroyed. The authorities ought not to be in this helpless condition. He contended that if a cargo of unsound food arrived in this country it ought to be in the power of the medical officer at the port to say that it should not be put upon the market. If this power existed not only would the poor be protected from the consequences of eating such food but small shopkeepers would be saved from the risk of having their reputations ruined through being prosecuted for exposing it for sale. Under the present Bill the Local Government Board would be able to stop such food at the port of entry. Only two port sanitary authorities at present—those of London and Manchester—had the power to deal effectively with food on landing, but this Bill would place Liverpool, Glasgow, and all the other towns in the same position and enable the port sanitary authority to inspect articles of food at the port, to take samples, and to destroy unsound articles. The regulations would also require satisfactory evidence as to the antecedents of the food such as was demanded by Germany, Denmark, and many other countries. They would insist upon the authorities knowing the conditions under which food was prepared, especially articles like sausages, brawn, and other things mainly consumed by the poor. Food would have to be stored in a clean and decent place. For example, ice-cream in process of preparation should not be kept under a bed or near a lavatory. Further, with regard to the distribution of food the regulations would insist that the receptacles, waggons, and other means of transport should be kept cleaner than they now were. Under existing conditions a medical officer was unable to go where he could obtain the information as to what went on in the preparation of food for human consumption, though it was well known that there were places in which food was prepared under the most insanitary conditions. Mr. Burns then quoted passages from a number of reports submitted by medical officers of health in support of the case for the Bill. One report from Finsbury stated that meat actually diseased, chiefly offal and veal, was imported even from countries where inspection took place. If the whole of this unsound food had been placed in waggons and transported from Finsbury to Battersea medical officers could not have stopped it in process of transit because it was not exposed for sale for human consumption. Another report stated that there were two vanloads of tinned meat in a very bad condition. When analysed the meat was found to be not cattle or sheep but horseflesh from Hamburg. Honourable Members could now realise what happened to the poor horses often seen in the streets of London going to the docks to be shipped abroad, and coming back after an interval as canned goods. In December, 1906, there were, according to the report of another medical officer of health, 11,000 tins of mixed food, the contents of which were putrid and unwholesome. The food was saturated with tin. The medical officer of Marylebone described a consignment of unsound meat in which the liver was filled with parasites and abscesses. THE LANCET, which deserved the greatest praise and credit for the way in which it had pressed the Government to do something in the direction proposed by the Bill, had said in an article in its issue of June 15th, 1907: "The trade in diseased meat and putrid milk, to say nothing of adulterated food-stuffs, will never be put an end to until the vendors are treated as the poisoners which they really are." He could give instance after instance to prove the truth of the comments of THE LANCET. He could give instances of human food treated with boric acid and so on. Therefore, he asked the House to give the Local Government Board not only the power to stop the sale of unsound meat but to enable the medical authorities to do legally what they could only now do by permission and bluff, amounting almost to intimidation. Proceeding to deal with the way in which the food of the poor was stored in some districts, he quoted official reports from the East End of London. These reports, set out that the sausage and brawn factories, mostly owned by Germans, were dilapidated places, badly lit, and often infested with rats In another instance beef was received in a filthy passage and hung on hooks against a filthy wall. Pickling tubs were placed in low-lying cellars; ice-cream was prepared in an open shed near a lavatory; and 70 cases of enteric had resulted from food which had been in a bedroom where children were suffering from that fever. Instances had been found where food was kept in the vicinity of a stable. He therefore appealed to the House to give his department power under the Bill to deal with this terrible evil. Whether tinned food came from Australia, Canada, the United States, Liverpool, or elsewhere, all dealers and manufacturers ought to be made to toe the line of one medical and sanitary standard. The right honourable gentleman went on to quote from a report made by Dr. G. S. Buchanan on tinned foods and that report showed that some of the food he examined contained bone and gristle, hog's bristles, and human hairs, and was dirty in addition. It might be said that since the recent exposures concerning tinned meat things had been put right and that there was no need for panic. Well, he could have got this Bill when the panic was at its height but he had thought it better to allow the panic period to pass before he brought it forward. He was satisfied that however perfect things might be now there was a strong probability that they would relapse to where they were. In proof of this he would read the following report which had been forwarded to him from a source which he would not now name. "I have the honour to inform you that I am told by the German Consul that the American meat packers have informed his Government that they are willing to agree to any inspection of meat required, on condition that what was rejected by the German officials is returned to them as it can be sold in the United Kingdom." He was not going to have that sort of thing. If we did not have the regulations provided for by the Bill there was the possibility that food rejected at German ports as unfit would be sent on by shippers to the United Kingdom. He was not going to allow diseased horseflesh to be sold in this country as "best Piccadilly brawn." This country ought not to take what other European countries would not take. He could give the House further instances to prove every statement he had made. All the local authorities were in favour of the Bill. He asked the House to give the Local Government Board power to make regulations and let the regulations be communicated to every sanitary authority. The regulations would not be enforced for 28 days after issue except in cases of emergency, so as to give all the interests affected time to make representations to the Local Government Board if they felt prejudiced by them. During those 28 days he would lose no opportunity of consulting with the trade. He hoped that in the interests of the consumers of the £40,000,000 worth of food that came annually into the country the Local Government Board would be given the powers embodied in the Bill. None but the dishonest trader in unsound food and the dirty manufacturer would have any reason to complain of the simple, necessary, and, he hoped, effective regulations that would be made.

Sir FRANCIS POWELL observed that the right honourable gentleman had made out a complete case for his Bill and he hoped that it would be placed on the statute book this session.

Sir WALTER FOSTER doubted if the machinery proposed by the Bill was adequate to deal with the magnitude of the evil described by the President of the Local Government Board. Food inspection to be carried out thoroughly and efficiently would necessitate hundreds of inspectors being employed and paid out of the rates. Under the existing law local authorities could have inspectors to attend markets and prevent diseased cattle from being sold and killed for food. Unfortunately local authorities would not help in this way. He hoped that the department would take steps to see that the local authorities were kept up to their work.

Mr. CAVE believed that the President of the Local Government Board had made out a very strong case for a Bill of this kind, but he urged that care should be taken that the regulations only applied to unsound food or the manufacture of food under insanitary conditions. He was afraid that the right honourable gentleman had effectually destroyed the appetite which any of them might have left for *pâté de foie gras* or for ice-creams.

Replying to other speakers, Mr. BURNS said that he was quite willing to turn the 28 days into 40 days and was prepared to lay the regulations on the table of the House for that period.

Mr. COOPER on this assurance withdrew his amendment.

The Bill was then read a second time and committed to the whole House.

TUESDAY, AUGUST 6TH.

Belfast Health Commission.

Mr. DEVLIN asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could state the probable date on which the report of the Belfast Health Commission would be issued; and whether it was proposed to issue any *ad interim* report.—Mr. BIRRELL replied (by a written answer): I understand from the chairman of the Commission that the report will probably not be ready before the end of September. It is not proposed to issue an interim report.

Exemptions from Vaccination.

In answer to Mr. LUPTON, Mr. JOHN BURNS said: The number of certificates of conscientious objection to vaccination received by vaccination officers in 1906 was 52,391.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.*

ARNOTT, W., M.B., B.S. Lond., has been appointed House Surgeon at the General Infirmary, Leeds.

BENTHALL, ALBERT, F.R.C.P. Edin., M.R.C.S. Eng., has been appointed by the Secretary of State under the Workmen's Compensation Act, 1906, a Medical Referee for Circuits Nos. 40 and 42.

BURTON, C. F., M.R.C.S. Eng., L.S.A., has been appointed by the Shipping Federation Examining Officer of Seamen at Whitby under the Compensation Act.

DAVIDSON, THOMAS, M.B. Edin., has been appointed House Surgeon at the Stockton and Thornaby Hospital.

DE SOUZA, D. H., M.B., B.S., B.Sc. Lond., has been appointed Demonstrator in Physiology at the University of Sheffield.

GOUGH, A., M.B., Ch.B. Leeds, has been appointed House Surgeon at the General Infirmary, Leeds.

GREENWOOD, F. G., M.B. Cantab., has been appointed House Physician at the General Infirmary, Leeds.

RODRIQUES, N. JOSEPH, L.R.C.P. & S. Edin., has been appointed Assistant House and Visiting Surgeon to the Stockport Infirmary.

TINLEY, W. E. F., M.D. Durh., has been appointed Certifying Surgeon under the Factory and Workshop Act in the Whitby District.

WALKER, M. G. L., M.B., Ch.B. Leeds, has been appointed Junior Resident Ophthalmic Officer at the General Infirmary, Leeds.

WRANGHAM, W., M.D. Lond., has been appointed Honorary Assistant Physician to the Bradford Royal Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNSLEY, BECKETT HOSPITAL.—House Surgeon. Salary £100, with board and lodging

BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and lodging.

BATH, BAILBROOK HOUSE.—Medical Superintendent. Salary £450 per annum, with extra payments, board for self and wife if married, quarters, laundry, and attendance.

BEDFORD COUNTY HOSPITAL.—House Physician. Salary £60 per annum, with apartments, board, and laundry.

BIRMINGHAM GENERAL HOSPITAL.—Three Receiving-room Officers. Salary £150 per annum.

BIRMINGHAM, QUEEN'S HOSPITAL.—House Physician. Also Obstetric and Ophthalmic House Surgeon for seven months. Salaries at the rate of £50 per annum, with board, lodging, and washing.

BOURNEMOUTH, ROYAL VICTORIA HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

BRADFORD SANATORIUM FOR CONSUMPTIVES, Eastby, near Skipton.—Resident Medical Officer. Salary £100, with rations, apartments, and washing.

is that on intracellular enzymes, which gives a glimpse into the inner working of cell activity by such agents as oxidases, catalase, alcohydrase, tyrosinase, and proteases. This leads to a study of the defence of cells against their autolytic enzymes and the relation of autolysis to metabolism, normal and pathological. In the resolution stage of lobar pneumonia we have a striking example of autolysis. The dissolution and removal of the dense contents of the alveoli are due chiefly to the leucocytic enzymes, while the lung tissue itself is protected by the immunity of living cells to digestive enzymes.

To the chemistry of bacteria and their products about 25 pages are devoted, including their enzymes, ptomaines, toxins, Ehrlich's conception of the nature of toxins, endotoxins, poisonous proteids, and pigments. Very full consideration (pp. 136–56) is given to immunity against bacteria and their products and the relations of agglutination and precipitation. The chemical nature of antitoxins is discussed and so are immunity against bacterial cells, bactericidal serum, opsonins, anti-enzymes, agglutinins, and precipitins. But the production of substances possessing the essential features of true toxins is not limited to the bacterial cell, for we have both *phyto-toxins* and *zootoxins*, to which Chapter VIII. is devoted. This naturally leads to the consideration of *cytotoxins*, hæmolysis, or more correctly "*erythrocytolysis*," since through usage the term hæmolysis has been limited to solution of the red corpuscles. The remaining 300 pages deal with the following subjects: Inflammation—a condition in which it seems most of the features of the inflammatory reaction are brought about by chemical substances produced by alterations in the tissue constituents at the point of injury. This chapter includes a discussion on chemiotaxis and phagocytosis. Then follow the chemistry of diseases of the blood and such allied phenomena as hæmorrhage, hæmophilia, anæmias and specific anæmias, leukæmia, thrombosis, embolism, and infarction (pp. 238–75), and a full discussion of the important subject of "œdema" (pp. 276–306). The retrogressive changes, including necrosis, gangrene, rigor mortis, parenchymatous degeneration, fatty amyloid, hyaline colloid, and mucoid degenerations—and also glycogen in pathological processes—are then dealt with (pp. 307–63). The classical division of fatty changes in tissues—as "infiltration" and "degeneration," introduced by Virchow in 1847—must, it appears, be given up. An enormous amount of literature has accumulated on this subject. It seems, however, that the fat accumulated in the liver during fatty degeneration is not derived, as Virchow thought, through a transformation of cell proteids into fat, but rather is an infiltrated fat brought in the blood from the fat deposits of the body to the disintegrating organ. This applies more especially to the liver, myocardium, and pancreas, the degeneration having been caused in the cells so infiltrated by the action of poisons or other injurious influences. "In the kidney, spleen, and muscles an increase of fat seldom occurs from these causes, but the cells may show a marked fatty metamorphosis through the setting free of invisible intracellular fat by autolytic changes" (p. 339). As to amyloid, it is never deposited in the cells themselves; it is infiltrated in the form of a soluble precursor and is not manufactured in the organ where it is found. In so-called "hyaline degeneration" there is no chemical compound "*hyalin*." The subjects of calcification, concretions, and incrustations occupy about 30 pages, while about 20 pages are devoted to pathological pigmentation.

The chemistry of tumours has been but little investigated, though the indications point to the chemical processes in them as differing but little from those in normal cells of similar origin. No substance, the author holds, has yet been isolated from, or detected in, malignant growths that is peculiar to them and not found in normal cells, and still less has any substance been detected that accounts in any way either for the occurrence of tumours or for the effects that they produce. The cachexia of cancer is in no way different from the cachexia of other conditions. The most favourable results of experiments on immunity against cancer "have been entirely unconvincing." The later chapters deal with abnormalities in metabolism, including auto-intoxication, and perhaps from the point of view of the general practitioner these are amongst the most important in the book. As to uræmia, we are told that "the experiments of Bouchard and his school present such serious errors of technique and interpretation that they are now largely disregarded," a view with which most observers will agree. This condition is due probably to the more toxic antecedents of the nitrogenous constituents of the urine and not to the substances themselves that are eliminated in the urine.

We have not space to refer to an excellent review of the leading facts and theories of such subjects as eclampsia, acute yellow atrophy of the liver, acid intoxication, chemical diseases of ductless glands, uric acid metabolism, gout, and diabetes. Enough has been said to show the wide scope of the work, the vast range of subjects, as well as the masterly mustering of the "scattered fragments." The author deserves the best thanks of the profession, not only for his labours—his successful labours of compilation—but for the conspicuous fairness with which he sets forth in terse, concise language the views of the various authorities. We feel sure that this work will not only provide a great storehouse of garnered knowledge on a difficult yet fascinating subject, but will serve to stimulate research as well as to guide treatment. We wish it the success which it assuredly deserves.

Practical Sanitation: A Handbook for Sanitary Inspectors and Others Interested in Sanitation. By GEORGE REID, M.A., M.D. Aberd., D.P.H. Thirteenth edition. London: C. Griffin and Co., Limited. 1906. Pp. 352. Price 6s.

THE introduction glances at the progress of sanitary work since 1844, giving some interesting tables showing the effect of the altered conditions on the death-rate. The facts are marshalled and the best practice relating to health questions is brought up to date. There is a chapter on water-supply and distribution, with a welcome one on warming and ventilation, which last subject is much neglected and often but little understood; others deal with sewerage, drainage, and sewage disposal, sanitary and insanitary work and appliances, house construction, infection and disinfection. The last chapter relates to food and the causes and detection of diseased conditions in the same. There is also a voluminous and most useful appendix of the principal statutes affecting the inspector of nuisances summarised by Dr. J. Herbert H. Manley, barrister-at-law. As will be seen, a very wide range of subjects is covered, all more or less associated with the work of sanitary inspectors, and details are given with which they are supposed to be familiar. When it is remembered that these men are paid some 50*s*. per week it seems doubtful if the salary is enough to command efficiency. Dr. Reid has fallen into a few of the pitfalls associated with plumbers' work; in Fig. 51 the water line in the trap is too far from the connexion of the closet. The same defect is shown in an exaggerated degree in Fig. 52. The slop water-closets (Figs. 62 to 65) would seem most unsavoury arrangements.

In discussing the difficulty of connecting lead pipes with iron or stone-ware ones Dr. Reid seems to have overlooked the brass sleeve piece in common use, while the treadle system recommended for urinals in private houses has generally proved unsatisfactory. Recent practice has improved upon the suggested trapping for lavatory basins when fixed in series. As these are usually found in rooms with

FRIDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (17th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (12th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—12 noon: Pathological Lecture:—Dr. Low. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations.

TUESDAY (13th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Lecture:—Mr. Pardoe: Treatment of Urethral Stricture.

WEDNESDAY (14th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Scott: Diseases of the Eye. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Dr. Moullin: Pelvic Hæmorrhage.

THURSDAY (15th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations.

FRIDAY (16th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.—Clinical Lecture:—Dr. Davis.

SATURDAY (17th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Scott: Diseases of the Eye. 2.30 P.M.: Operations.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1907, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(*Taken daily at 8.30 a.m. by Steward's Instruments.*)

During the week marked copies of the following newspapers have been received:—*Liverpool Daily Post and Mercury, Surrey Advertiser, Yorkshire Post, Herefordshire Mercury, Newcastle Daily Chronicle, Manchester Guardian, Manchester Dispatch, Hull Mail, Manchester Chronicle, Daily Telegraph, Army and Navy Gazette, Westminster Gazette, Glasgow Evening Times, Glasgow Herald, Literary Digest, &c.*

and Dr. Leslie Roberts his articles on Seborrhœa. Dr. Ernest E. Glynn discusses the subject of Pulmonary Embolism and Thrombosis, holding that the latter is often the actual occurrence in cases of sudden death.

The Birmingham Medical Review.—The July number of this review contains the second Ingleby lecture by Dr. Thomas Wilson, dealing with Pelvic Inflammations in the Female, the present lecture being devoted to puerperal infections and their treatment and to gonococcal and chronic pelvic inflammations. This lecture was published in THE LANCET of July 6th. Dr Smallwood Savage contributes a valuable paper on Vaginal Cæsarean Section as treatment for conditions in which there is undilatable or imperfectly dilated cervix. He gives notes of two cases in which he made use of this method, first suggested by Dührssen—viz., one of epithelioma of the cervix and one of placenta prævia. The paper deserves careful perusal.

The Medical Chronicle.—The principal article in the July number of this magazine is an abstract of a thesis by Dr. George G. Packe on Cancer of the Stomach, founded on a study of statistics derived from the post-mortem records of St George's Hospital. The author concludes that primary cancer arises more frequently in the stomach than in any other internal organ, and that there has been a greater increase in the incidence of the malady on this organ than on any other part of the body. Syphilis and tuberculosis seem to be antagonistic to the development of this form of cancer or, at all events, rare concomitants or antecedents. Mr. E. D. Telford records a case of Acute Dilatation of the Stomach but throws no light upon the causation of the condition.

The Middlesex Hospital Journal.—A very entertaining article on Some Experiences in China, written by Mr. Dansey Smith of the Wesleyan Mission Hospital, Wuchow, appears in the July number of this journal. Anecdotes are given of the superstitions, medical and otherwise, prevalent among the Chinese, of their wonderful powers of recovery from injuries, and of the experiences of a European medical man among them. Mr. Somerville Hastings relates two cases in which trial was made of thiosinamin—one of keloid after burns in which no good effects were produced and one of chronic indurative ulceration of the leg in which the treatment was apparently beneficial.

MEDICINE AND THE LAW.

Three Criminal Cases: Richard Brinkley, Marie Leslie, and Charles Smith and May Churchill.

THREE criminal trials, taking place during the same week have recently attracted a considerable measure of public attention and have all presented medical features. Richard Brinkley, who was executed on Tuesday last, attempted to poison a man for whose removal he had a well-proved motive, by putting before him a bottle of stout into which he (the prisoner) introduced prussic acid after he had himself drunk from the bottle. Two persons against whom Brinkley had no design drank the stout instead of the man for whom it was intended, so that the latter remained alive to give evidence against his would-be murderer. A feature of note in this case was the ease with which the prisoner had obtained a considerable quantity of prussic acid. It was suggested that he had stolen it, or some of it, from a man described as a "specialist in the diseases of birds, who also treated dogs and cats." This "specialist" stated that he had on two occasions given Brinkley about 60 drops of prussic acid in response to a story that he wanted to poison a neighbour's dog, and that he had also left him alone in the room where the drug was kept in such circumstances that he might have helped himself to it. This points to a dangerous state of affairs capable of existing in spite of the precautions prescribed by the law with a view to control the trade in poisons. A similar point in connexion with Brinkley has been mentioned since his trial. It has been stated that 14 years ago an inquest was held upon a girl with the result that the jury found that she had committed suicide, the evidence showing that if she did so it was with arsenic taken by her from a box in Brinkley's room. In this box were found prussic acid, arsenic, strychnine, and chloroform, for which he accounted by a story that he was engaged upon chemical research in connexion with photography and electrical engineering. The acquisition of such a deadly armamentarium by a murderously minded individual affords a striking commentary upon the working of the laws regulating the sale of poisons. He also stated that he had given the girl shelter, after which she had cohabited with him. Without being uncharitable we may surmise that Brinkley was at that time an object of considerable suspicion to the police, but there seems to have been corroboration of his story that the deceased girl broke into the box which contained the poisons mentioned. He was evidently a man who had obtained some knowledge of poisons and it seems probable that he had studied them with a deliberate intention of using them criminally, for after he had denied this in cross-examination a piece of paper which had been found in his possession was put into his hand by counsel. It contained the following note: "Nitrate of silver with ordinary water will turn the water milky, but if it is put into distilled water the water undergoes no change." It was suggested by the prosecution that this information was intended to be used in order to administer poison to an unsuspecting victim. Brinkley's explanation was that the "specialist" already mentioned had supplied him with it as a test for distilled water as he (Brinkley) always drank distilled water at home, and he wished to be able to ascertain whether the druggist was really providing him with this somewhat unusual beverage for a working carpenter.

The second case referred to above, that of the woman Leslie, who was convicted of obtaining large sums of money by false pretences from exceedingly foolish dupes, is to be noted on account of the course adopted by Mr. Justice Darling, who expressed himself in accord with the suggestion of her counsel that her crime was that of a person not responsible for her actions. His lordship allowed a verdict of guilty to be returned in the ordinary way, and indeed there was no evidence before him to justify any other, and he then passed a sentence of five years' penal servitude, but in doing so he dwelt upon the character of her crime which was one absolutely certain to be discovered almost immediately. To this he added that he thought she needed to be kept under control for a considerable time but that he should leave the question of how long she was to be detained and of how she was to be treated to the Home Secretary. It seems certain that this woman was lacking in the normal powers of restraint which prevent the individual from doing an action immediately advantageous to himself on account of future greater disadvantages, and such a marked instance of this lack of inhibition comes very near insanity. We can understand, however, that the judge's expressions in regard to Marie Leslie may be considerably quoted, and strained in the process, in defence of other persons.

The third of the cases mentioned, that of Charles Smith and of the woman notorious as "Chicago May," was remarkable for the fact that the accused and their intended victim, Guerin, were all professional criminals, good examples of their class. The actual crime could hardly have been committed by persons in their "right mind," even though that mind was naturally prone to crime. The motive claimed by the prisoners themselves was the protection of the woman against an attack which they declared was intended against her by Guerin. Whether they really feared this, or whether Churchill planned Guerin's death in order to revenge herself upon him for leaving her in favour of another woman, to pursue a man and to shoot him in the open street with a revolver in circumstances which rendered their immediate capture almost a matter of certainty was an extraordinary course for experienced criminals to adopt, even when to some extent under the influence of alcohol. It has been stated that Churchill was a victim of the opium habit and, in any case, she and Smith, as well as Leslie and Brinkley, offer interesting subjects of study for the criminologist.

A Lecture
ON
THE PRINCIPLES OF VACCINE-THERAPY.

Delivered before the Harvey Society of New York

By Sir A. E. WRIGHT, M.D. Dub., F.R.S.,
SOMETIME PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY; DIRECTOR IN MEDICAL CHARGE OF THE DEPARTMENT FOR THERAPEUTIC INOCULATION, ST. MARY'S HOSPITAL, LONDON, W.

INTRODUCTORY.

GENTLEMEN,—I have undertaken to outline to you to-night —so far as I can do so within the limits of a single lecture—the principles of vaccine-therapy—i.e., of the treatment of bacterial disease by the inoculation of the corresponding vaccines. Let me preface what I have to say to you on this subject by asking you briefly to review with me the methods —other than vaccine-therapy—which we have to-day at disposal for the treatment of bacterial disease. The following are, I think, the only methods which come here into consideration: (1) treatment by chemical antiseptics; (2) treatment by the extirpation of the obtrusive focus of infection; (3) treatment by the determination of lymph to the focus of infection; (4) serum-therapy; and (5) expectant treatment.

1. TREATMENT BY CHEMICAL ANTISEPTICS.

Antiseptics have found in medicine a threefold application. They have been locally applied with a view to holding in check and extinguishing localised bacterial infections. They have been used for the purpose of checking putrefaction in discharges and devitalised tissues. They have been administered internally with a view to checking microbial growth in the blood or in regions which can be reached only by the channel of the blood. Neither the second nor the third of these applications calls for any discussion. There has never been any doubt as to the possibility of suppressing putrefactive changes by antiseptic irrigations. And it is now all but universally recognised that it is futile to attempt to check bacterial growth in the interior of the organism by antiseptics which have—as our present antiseptics have—a greater affinity for the constituent elements of the body than they have for any bacteria.[1] Attention may therefore here be concentrated upon the issue as to whether the antiseptic applications are effective in holding in check and extinguishing localised bacterial infections.

It is, of course, currently believed that this method of treatment is effective. It is in this faith that the surgeon introduces antiseptics into septic wounds or, where he happens to be so minded, into abscess cavities. It is in this faith that the physician resorts in the case of pulmonary infections to antiseptic inhalations. And it is in this faith that the dermatologist, gynæcologist, laryngologist, aurist, and genito-urinary specialist are each strenuous—in the application of antiseptics to the particular province of the body which he takes under his care. It will be profitable for us to collate the facts and to consider whether there is in reality any trustworthy basis for the belief that inspires all this practice.

Significant in this connexion appears to me the fact that antiseptics are now by general consent abandoned in connexion with the treatment of ordinary surgical wounds. Significant also is it that the practice of introducing antiseptics into abscess cavities—erstwhile so common—is now less and less frequently resorted to. Significant, again, is it that treatment by antiseptics in case of bacterial invasions of mucous membranes is to-day more and more frequently followed up by curetting, scraping, and so-called 'radical' operations. Above all significant, is it that so distinguished a dermatologist as Sabouraud should sum up the results of antiseptic treatment of bacterial diseases of the skin as follows: "Curious, indeed, is the failure of antiseptics in connexion with the treatment of bacterial diseases of the skin. Quite colossal were the expectations which were entertained with regard to what would be effected. What has actually been accomplished by antiseptics amounts in point of fact to almost nothing." The results which have been obtained in connexion with pulmonary infections by antiseptic inhalations and in connexion with bacterial infections of the genito-urinary passages by 'urinary' and other antiseptics are, I am persuaded, neither better nor worse than those which have been obtained in connexion with diseases of the skin.

Now all this failure of antiseptics is, I submit, only what might *a priori* have been expected. Let me put the case to you as I see it. It is, of course, axiomatic that antiseptics can take effect only upon those bacteria with which they come into contact. It is obvious also in the case of bacterial infections of the skin and mucous membranes that the infecting bacteria will not all be lying on the surface, and that they will not, when lying on the surface, be limited with respect to their distribution to those regions which are accessible to antiseptics. It follows that it will be quite unreasonable to expect from any application of antiseptics a complete sterilisation. In every case a residue of bacteria will survive. These will inevitably multiply and reoccupy the disinfected surface.

And this is not all. The antiseptic will not, as the unthoughtful assume, add its antibacterial power to the antibacterial power of the living organism. On the contrary, the antiseptic will directly antagonise the protective forces which the living organism has at command. It will paralyse the phagocytes, and will abolish the antibacterial power of the blood fluids. The disinfected surface will thus, by the action of the antiseptic, be left 'swept and garnished,' to await reoccupation by the expropriated bacteria.

And, again, this is not all. The antiseptic application will also injure the histological elements and, in particular, the capillaries of the tissue to which it is applied. It will thus lead to an outpouring of lymph from the disinfected surface. That outpouring will not only wash away the antiseptic, but it will, where a skin surface is in question, convert the natural dry keratin armour of the normal epidermis into a sopping, lymph-sodden blanket in which bacteria will easily establish themselves.

2. TREATMENT BY THE EXTIRPATION OF THE OBTRUSIVE FOCUS OF INFECTION.

In the case where the invading bacteria have penetrated into the interior of the body their destruction by antiseptic applications will be obviously out of question and the policy of proceeding against the bacteria by surgical methods will come up for consideration.

I can understand that extirpation may be imperative where an organ has been completely disorganised by invading bacteria and where there is danger to life from the spread of the infection. I can understand, also, that a case can be made out for extirpation where there is prospect of removing all the infecting bacteria without danger or sensible mutilation. Lastly, I can understand that it will be an added advantage if an extirpation operation removes along with the infecting bacteria a useless organ which is specially subject to infection. But assuredly these are not the conditions under which the majority of scraping and extirpating operations are undertaken. And in particular these are not the conditions which confront us in those extirpation operations which are employed as a routine treatment in connexion with localised tuberculous infection. Here long before the surgeon has been called upon the scene many of the bacteria may, by the agency of the blood and lymph stream, have been carried beyond reach of his knife.

It will be clear that it cannot be claimed for extirpation operations undertaken in these circumstances that they are in any real sense of the term 'radical operations.' They are operations which aim only at the extirpation of one or more obtrusive foci of infection. In harmony with this conclusion is, I submit, the fact that tuberculous disease so often recurs after operation—exceptionally, in the form of general tuberculosis; commonly, as a localised process in the site of the operation, or elsewhere. Such results would at first sight appear to be adequately explained by the mechanical disturbance in the focus of infection, or by the incomplete character of the operation. But probably there is at work here also another factor. A reduction in the antibacterial power of the blood may, as we shall see, supervene upon operative interference.

3. TREATMENT BY THE DETERMINATION OF LYMPH TO THE FOCUS OF INFECTION.

The method of extirpation by the knife is only one of the methods which can be employed for the treatment of bacterial

---

[1] We have a general formula for such antiseptics when we say, in technical terms, which perhaps improve a little on those of Ehrlich, that they are [illegible] than "parasitotropic."

BRITISH MEDICAL ASSOCIATION.

MEETING AT EXETER.

THE SECTIONS.

MEDICINE.

Friday, August 2nd.

Discussion on Rheumatoid Arthritis and the Morbid Conditions which Simulate it, with Special Reference to Pathology and Treatment.

Dr. **Arthur P. Luff** (London), in opening the discussion, pointed out that the term "rheumatoid arthritis" was objectionable, as suggesting a causal connexion with rheumatism. If, however, it was employed to mean an arthritis somewhat resembling some forms of rheumatism, the term might be retained, although the name "arthritis deformans" was less open to objection, but he suggested that in that discussion the term "rheumatoid arthritis" should be retained owing to its long usage. In opposition to those who regarded rheumatoid arthritis as a very complex disorder with many factors concerned in its etiology he held that although there were several infective diseases of the joints which somewhat resembled it, yet that rheumatoid arthritis was a distinct clinical entity. It was a constitutional disease, not a local one, the affection of the joints being only a part of the morbid process. He regarded it as a disease due to micro-organisms gaining access to the blood in the majority of cases probably through some chronic catarrh of the alimentary tract, although the invasion might occur from the nose, pharynx, or air tubes. They found their way to the joints where they produced inflammatory changes resulting in ulceration, erosion, destruction, and, coincidently as a rule, in hypertrophy also. During their growth toxins were produced and discharged into the circulation, giving rise to the nervous symptoms of the disease and producing the local sweatings and pigmentation associated with it. That it was an infective disease was shown by the febrile disturbance which always accompanied the early stages of the disease, by the rapidity of the pulse, the local sweatings, and by the progressive involvement of many joints. In its early stages it might very closely simulate subacute rheumatic fever but it might be distinguished from it by not reacting to treatment with salicylates. It usually commenced in one joint and then rapidly spread to others. Shortly after its commencement it was always polyarticular. He was of opinion that the so-called forms of monarticular rheumatoid arthritis were always traumatic in origin. It would be better to restrict to these forms the name "osteo-arthritis." Rheumatoid arthritis occurred in two forms—acute and chronic—both being due to the same infective cause. It was commoner in females than males. In the acute form it was generally met with in earlier adult life. The chronic form might be a later stage of the acute disease, or, as was more frequently the case, it might be chronic from the first. It occurred in middle life and in females, especially about the climacteric period. Comparatively slight injuries of a joint, especially of a small joint, might lead to rheumatoid arthritis. The injuries were frequently the outcome of excessive work and strain, especially in elderly and enfeebled persons with a diminished power of resistance. In the acute form the synovial membranes were primarily and mainly affected, while the ligaments were softened and infiltrated, presenting the well-known spindle-shaped enlargements of the joints. The cartilages were damaged secondarily, and it was not until the disease had assumed the chronic form that the signs indicative of destruction of cartilage became evident, accompanied with cartilaginous and osteophytic outgrowths. Cases of Heberden's nodes represented the mildest degree of the disease. They were due to a very chronic form of rheumatoid arthritis. This type was more commonly met with in women than in men, and usually at or after the middle period of life. The nodules were due to enlargement of the ends of the bones, which were frequently covered by a pouch of the projecting synovial membrane, acting somewhat as a bursa. In the great majority of cases rheumatoid arthritis was a primary disease, but it was probable that in a small number of cases an antecedent attack of rheumatic fever, or of some form of septic arthritis, such as gonorrhœal arthritis, or even an acute attack of gout, might have left the joints in such a vulnerable condition that they might subsequently become the seat of true rheumatoid arthritis. Dr. Luff protested against the tendency to invoke uric acid as a cause of the joint condition in this disease. Any debilitating condition might predispose to this disease, and especially of late years he had seen many cases of rheumatoid arthritis which had followed repeated attacks of influenza. Rheumatoid arthritis, if left untreated, tended to spread from joint to joint and produced progressive destruction of the joint tissues. For the successful treatment of this disease it was essential that the treatment should be commenced while the disease was in its early stages; hence the importance of an early recognition of the malady and of its distinction from gout and rheumatism. The treatment must be persevered in for a long period of time, generally a year or two, and during the treatment everything possible must be done to improve the general condition of the patient. If rheumatoid arthritis was seen and recognised early in the acute stage it was curable. In the later chronic stages it was possible to arrest the disease, to remove the pain, and to secure greater movement of the joints, but not to restore them to their normal state. The not infrequent mistake of diagnosing rheumatoid arthritis as gout and the consequent placing of the patient on a restricted and spare diet had undoubtedly led to the development of severe and incurable forms of the disease. It was essentially a disease that required good and nutritious feeding. The diet should be as liberal and as good as the patient could digest and animal food should be partaken of freely, though not to the exclusion of vegetables. A moderate quantity of wine or stout should be taken with lunch and dinner. The drugs recommended by Dr. Luff were guaiacol and potassium iodide. He had employed guaiacol in over 3000 cases and as the result of his experience he did not hesitate to say that, if administered in sufficient quantities and for a sufficiently long period, it was capable in the great majority of cases of arresting the disease, of diminishing the size of the joints, of permitting increased movements, and of relieving pain. It was useful in both the subacute and chronic forms of rheumatoid arthritis. He believed that the guaiacol exercised an inhibiting effect upon the micro-organisms responsible for the production of rheumatoid arthritis. Guaiacol should be given in cachets in the form of the carbonate. At first from five to ten grains of the carbonate of guaiacol should be given three times a day and the dose should be increased by one to two grains each week until from 15 to 20 grains were being taken in each dose. It was essential that this treatment should be continued for at least 12 months. The beneficial effects of the guaiacol were very much increased by administering at the same time a mixture containing potassium iodide, the depressing effect of the iodide being counteracted by its combination with tonics. This treatment yielded much better results than prolonged treatment with arsenic and iron. If the treatment was commenced in the comparatively early stages of the disease then recovery with very little deformity might result; but even if after arrest of the disease much deformity resulted, very considerable mobility of the joints might be promoted by baths, superheated air, massage, and passive movements. Douche massage was the most effective form of treatment with hot water, and perhaps next to that ranked peat baths and brine baths. Electric light baths, in which the affected joints were bathed in the heat and light rays reflected from a number of incandescent electric lamps, were also beneficial in many cases. Regulated movements and massage were of great use in overcoming the stiffening and fixation of the joints and the muscular wasting in their vicinity. In regard to climate, dry heat benefited cases of rheumatoid arthritis whereas damp cold increased the disease. Seaside resorts were not suitable for most cases. As a winter resort there was no better climate than that of Egypt.

Dr. **T. S. P. Strangeways** (Cambridge) stated that he was engaged at Cambridge on a research into the pathology and etiology of the disease, which he did not regard as a clinical entity but as a type. He regarded rheumatoid arthritis as a heap to which any joint disease was thrown which was not understood. He expressed himself as emphatically disagreeing with most of Dr. Luff's statements. A study of the literature and of the clinical notes of cases was practically valueless owing to the various different diseases of joints recorded under this heading.

of the fact that they are capable of ingesting bacteria and of disintegrating these by intracellular digestion. We may usefully distinguish between '*spontaneous*' and '*induced*' phagocytosis. By the former of these terms we may denote that process of ingestion which comes under observation when bacteria which have not been subjected to the action of the blood fluids are brought in contact with washed leucocytes in an indifferent medium such as physiological salt solution.

Spontaneous phagocytosis as here defined is distinguished by the fact that it is a comparatively slow process; further, by the fact that the number of bacteria ingested by each leucocyte attains ordinarily only very modest proportions; again, by the fact that the ingestion is irregular in the sense that individual polynuclear leucocytes differ very strikingly from their congeners with respect to their intake of bacteria—the majority picking up from such a bacterial suspension as is ordinarily employed very few, if any, bacteria, while others ingest relatively considerable numbers; and lastly, by the fact that the ingestion of bacteria can be completely suppressed by employing in the phagocytic mixture certain concentrations, in the case of the tubercle bacillus a concentration of slightly over 1 per cent., of NaCl.

Strikingly different from such 'spontaneous phagocytosis' is the *induced phagocytosis* which comes under observation when leucocytes are brought in contact with bacteria which have been, or actually are at the moment, subjected to the action of serum. The 'induced phagocytosis' which occurs in these conditions is distinguished, first, by the fact that it is an exceedingly rapid process; secondly, by the fact that every adult leucocyte, with hardly an exception, is here phagocytic (instead of some few leucocytes taking part immoderately, while the others abstain); thirdly, by the fact that the leucocytes will, in the case where the supply of micro-organisms is unrestricted, ordinarily fill themselves to absolute repletion; and fourthly, by the fact that the leucocytes will continue to ingest bacteria in a concentration of salt which entirely suppresses 'spontaneous phagocytosis.'

Seeing that phagocytosis of bacteria without subsequent intracellular digestion would, from the point of view of the protection of the organism, be meaningless, it will be plain to you that the digestive powers of the leucocytes would logically here come up for consideration. Into such discussion I am, however, for the present debarred from entering, not having as yet qualified myself to speak at first hand on the matter. Permit me none the less to give here my tribute of admiration to the brilliant initiating work which has been done on this subject by your fellow member, Dr. Opie.[2]

(*b*) *Antibacterial elements of the blood fluids.*—The blood fluids differ essentially from the nutrient fluids which are ordinarily employed by the bacteriologist for the cultivation of micro-organisms in the respect that, while the latter are nutrient fluids pure and simple, the blood fluids contain in addition to nutrient *constituents* also antibacterial elements.

The antibacterial elements which are here in question are "bacteriotropic elements" in the *sense that* they turn towards and enter into combination with elements of the bacterial body. Our knowledge of the modifications which are effected in the bacterial body under the influence of the bacteriotropic substances in the blood fluids is, it cannot be doubted, extremely incomplete. So much, however, already stands fast that the effect of the blood fluids upon the bacterial body may manifest itself in different ways. The bacteria may be killed without being dissolved. The bacteria may not only be killed but dissolved. We may group these together as bactericidal and bacteriolytic effects. The bacteria may be so altered as to agglutinate in the presence of salt (agglutination effect). The bacteria may be so altered as to be readily ingested by phagocytes (opsonic[3] effect).

Inasmuch as the blood fluids produce in bacteria the different chemico-physical effects here enumerated, and inasmuch as agglutinating and opsonic effects can be obtained independently of each other, and independently of any bactericidal and bacteriolytic effects, we may assume that we have in the blood fluids in addition to bactericidal substances (or bactericidins) and bacteriolysins also agglutinins and opsonins. Of these four varieties of bacteriotropic substances the opsonins appear to be the most important. We may ascribe to them a predominating importance, first, because it can be shown that the opsonic effect is, by either the normal or immune blood, exerted upon every species of bacteria, whereas the agglutinating effect is exerted only upon special varieties of bacteria, and the bactericidal and bacteriolytic effect among pathogenic micro-organisms apparently only upon the typhoid bacillus and the cholera vibrio.

The opsonins derive further practical importance from the fact that they can be very accurately measured (the error of estimation in the case of normal bloods and in the hands of a good worker being rarely greater than plus or minus 5 per cent.) and that it is possible, seeing that the opsonic effect of the normal blood fluids is very marked, to register not only (as in the case of the agglutinating power) an increase but also a reduction in the opsonic power of the blood. Such increase and reduction in the opsonic power of the blood are, as you will of course understand, measured by comparing the amount of purely induced phagocytosis which is obtained with a normal blood with the amount of purely induced phagocytosis which is obtained with the blood of the patient under examination.

From the consideration of the protective machinery of the organism let me now turn to the consideration of certain preliminary points in connexion with the bacterial vaccines which operate upon that machinery. The first question which confronts us here is the question as to how far the success of an inoculation process is dependent upon the particular composition of the vaccine. I have in view here in speaking of the particular composition of the vaccine not the axiomatic requirement that it must be affiliated to, or connected by affinity with, the microbes which it is designed to combat, but rather the minute details with regard to its source and manufacture.

The Question as to How Far the Particular Composition of the Vaccine is a Material Element in the Success of an Inoculation Process.

Reflection will make clear that the success of an immunisation process must depend, in the first place, upon the power of immunising response which the organism may happen to possess with respect to the particular bacterial infection or intoxication process which is in question, and, in the second place, upon (*a*) the composition of the vaccine and (*b*) the dosage and method of administration. Up to the present the composition of the vaccine has been considered to the practical exclusion of the question of dosage. Whenever ill-success has attended a process of immunisation, or whenever it has appeared to any one that it "ought" to be possible to improve upon the result already obtained; straightway the suggestion has been put forward that some change "ought" to be made in the composition of the vaccine. In such cases living vaccines have been proposed as substitutes for sterilised vaccines; vaccines derived from virulent cultures as substitutes for vaccines derived from avirulent cultures; vaccines derived from cultures more closely affiliated to the microbes against which protection is sought as substitutes for vaccines obtained from cultures less closely affiliated; vaccines derived from agar cultures for rheumatism and cases in which both had a share, all cases due to syphilis or tuberculosis, all those of gonorrhœal origin, and the condition of tabetic arthropathy, there was still a residuum of cases left which might be called rheumatoid arthritis. He alluded to the cases in children described by Dr. G. F. Still in which, in addition to the joint changes, there was also enlargement of the spleen and of the lymphatic glands—a condition which, he thought, must be microbic in origin. Another class of case was that occurring in young adults, chiefly women, with an onset like that of true rheumatism, and some of these cases he believed to be distinctly rheumatic. He recommended doses of salicylates in these cases of what might be regarded as of heroic magnitude—viz., up to as much as 300 to 400 grains a day given in ten doses. He began with small doses, increasing until toxic symptoms developed, then withholding the drug for three or four doses and beginning again with half the doses and again increasing rapidly. With each dose twice as much bicarbonate of sodium was given as salicylate. In regard to the chronic type with enlargement of many joints, he was of opinion that one cause in women was the limitation of the water taken into too small an amount daily.

---

[2] Since the date of this lecture I have corroborated the results of Opie and have found a method of displaying his results by the aid of leucocytes obtained from blood drawn from the finger. It may perhaps be of interest to subjoin here the technique I have employed. It is modelled upon the inoscopic methods of Jousset. A capillary pipette which is fitted with a rubber teat is taken in hand. A puncture is now made in the finger, and one volume of blood—a quantity of from 10 to 20 cubic millimetres is quite adequate for our purposes—is aspirated into the stem of the pipette. We now, filling up each time to the same mark, aspirate into the pipette four equal volumes of distilled water, and mix these *four* volumes of water with the one volume of blood in the neck of the pipette. By this manœuvre we hæmolyse all the red corpuscles, leaving the white corpuscles intact. We now place the pipette in an incubator at blood heat and keep it there for some ten or more minutes. The diluted blood will now have coagulated in the neck of the pipette. Our next step is to fill in another pipette with physiological salt solution and to project this in the form *of* a stream upon the coagulated blood. We continue this process till the clot has contracted firmly upon the white corpuscles which are held in suspension in its meshes, and till every trace of serum has been washed away. We now remove the last traces of our wash water and fill into the pipette a quantum of liquefied 20 per cent. gelatin equivalent to twice the *original* volume of blood. Finally, we seal up the tube in an air-tight manner and place it in an incubator regulated so as to maintain a temperature of about 50° C. After an interval of from 24 to 48 hours we find that the clot has undergone autodigestion and that the gelatin surrounding the clot has lost its power of solidifying on cooling. We verify, in the case of a control tube which has been treated in exactly the same manner except in the respect that it has received a small addition of serum, that these changes do not occur in the presence of serum. The whole procedure is of course carried out in an aseptic manner.

[3] Derived from the Greek οψωνεω, and the Latin opsōno,—*I convert into palatable pabulum.*

Dr. F. J. POYNTON (London) stated that, working with Dr. A. Payne, he had isolated a micrococcus from a joint and by it produced a rheumatoid arthritis in rabbits. Working with the rheumatococcus he had also found that it could produce a periarthritis and an osteo-arthritis, as well as a synovitis. He differed from Professor McCrae and thought that rheumatoid arthritis could be of rheumatic origin. He also believed in the old view as to some cases being of gouty origin and thought that the gouty inheritance afforded a good soil for the exciting agent of rheumatoid arthritis.

Dr. A. W. SIKES (London) agreed with Dr. Poynton as regards the relationship which might exist between these cases and rheumatism and gout. He referred to the four groups of causes usually admitted—viz., metabolic disturbances, gastro-intestinal derangements, nerve conditions, and bacteria. He thought physical exercises were of value and had seen cases of slight rheumatoid arthritis of the knees improved by bicycling.

Dr. E. L. FOX (Plymouth) disagreed with Dr. Davy in regard to the rarity of the disease in Devonshire, for he had seen most severe cases of it in Plymouth. He regarded drugs as practically useless.

Mr. J. W. DRAPER (Huddersfield) agreed with Dr. Tyson as to the bad effect of damp in houses and the value of concreting the floor.

Mr. V. T. GREENYER (Hove) called attention to the value of opening the joints and washing them out.

Dr. W. ODELL (Torquay) had seen good results from the salicylates in certain stages. He believed in the use of guaiacol and hypophosphites and had seen good results from the administration of tablets of ichthyol.

Mr. T. MORRELL THOMAS (Newport, Mon.) recommended the breaking down of adhesions under ether.

The PRESIDENT of the section, Dr. W. GORDON (Exeter), expressed his gratification at the valuable nature of the discussion. He confirmed the value of guaiacol carbonate in the treatment of the disease.

Dr. LUFF, in reply, confirmed the remarks of Dr. Davy in regard to the importance of early diagnosis. He differed from Dr. Lees in regarding the reaction of any case to salicylates as definitely establishing it as rheumatism, since in his opinion true rheumatoid arthritis was not benefited by them. The use of Bier's method was of value only when a few joints were affected. He had found Dr. Latham's method of value only in cases of spinal arthropathies.

SURGERY.

THURSDAY, AUGUST 1ST.

Mr. J. BLAND-SUTTON (London) opened a discussion on

The Indications for Cholecystectomy

by saying that it was now fully decided that bile was purely excrementitious. The liver was an organic filter for the blood of the portal vein, removing from it not only toxins but also microbes which had been absorbed from the gastro-intestinal tract. Observation failed to show that in a healthy gall-bladder any chemical change took place in the bile, except an alteration of colour and a slight admixture of mucus. Observation and experiment taught them that gall-stones were the result of pathological changes of the walls of the bile-ducts and gall-bladder. It was formerly thought that these changes were due to direct infection from the duodenum through the common bile-duct, but it was now known that the worst forms of cholelithiasis, cholangitis, and cholecystitis were due to toxins and germs which had been excreted by the liver with the bile. It must also be recognised that anything that caused stasis of the bile favoured the formation of gall-stones and also it was important to note that in 75 per cent. of all cases of gall-stones they had originated in the gall-bladder. The functions of the gall-bladder were of very little importance. Anatomy, human and comparative, taught them that absence of the gall-bladder entailed no disadvantage. Observations on the dead showed that disease destroyed it very often without causing any inconvenience to the individual. Pathological observations and the experience of surgeons were equally eloquent in proclaiming the dangers and catastrophes accompanying many diseased conditions of the gall-bladder which might be obviated by a timely operation, and the accumulated experience of many surgeons showed that the most satisfactory consequences were obtained by treating the gall-bladder, when it required surgical intervention, in the summary fashion in which they now dealt with the vermiform appendix. The morbid conditions of the gall-bladder which were best suited for cholecystectomy were: (1) Injury to the gall-bladder; (2) calculous cholecystitis; (3) acute (non-calculous) cholecystitis; (4) perforating ulcers of the gall-bladder; (5) mucocele (hydrops vesicæ felleæ); (6) chronic cholecystitis (empyema); (7) biliary fistula; and (8) primary cancer, sarcoma, and endothelioma of the gall-bladder. In a case of injury removal was much the best operation; the organ was damaged and removal was easy. When calculi were present in the gall-bladder it was certain that the mucous membrane of the gall-bladder was diseased; and as most calculi came from mucous catarrh of the bladder, if the gall-bladder was left there was a chance of recurrence of the disease, while if it be removed recurrence could not occur. Again, in some cases of gall-stones in the gall-bladder the cystic duct became obliterated and in such a case it was obvious that removal must be the correct treatment. In all cases of removal of the gall-bladder it was necessary to be absolutely certain that the common bile-duct was pervious. In acute non-calculous cholecystitis it was equally advisable to remove the gall-bladder, for the damage to the mucous membrane could not be completely recovered from, just as in an acute appendicitis the appendix must be removed. Perforating ulcers of the gall-bladder could be divided into those occurring (1) in calculous cholecystitis, (2) in the process of the formation of a fistula, and (3) in cholecystitis without calculi; these were the simple forms, but it might also occur from typhoid ulceration and in the final stage of malignant disease of the gall-bladder or bile-ducts. The signs of perforation were those usually met with in perforation of hollow abdominal viscera and in most cases it was diagnosed as due to a perforating appendicitis in an unusual situation. When perforation had occurred it was better to remove at once the gall-bladder and not to make any attempt at closing the perforation. A mucocele of the gall-bladder was often called hydrops; in this condition the cystic duct was blocked and the bladder might be distended to almost any size. The mucus might be thin or it might be thick; in the latter case if gall-stones were present they might be described as "in aspic." Sometimes a rod-like stone occupied the centre of the gall-bladder and around it was the mucus. Excision gave good results in mucoceles. Sometimes the patient might be perfectly well in a fortnight. When cholecystitis became chronic pus collected and an "empyema" was formed, or a mucocele might become infected. In these cases of abscess of the gall-bladder complete immediate removal was far better than drainage. When suppuration occurred in other similar viscera removal was now the recognised treatment, as in pyonephrosis, pyosalpinx, and suppurating ovarian cysts. Fistulæ might arise in two ways: they might be spontaneous or they might be the result of an operation. If bile was discharged from the fistula, then it was certain that the common bile-duct was blocked; if only mucus was discharged then the cystic duct was blocked. The surgeon must be sure that the common bile-duct was clear before he attempted to remove the gall-bladder. For primary malignant disease of the gall-bladder removal was the best treatment if the case was seen early, but clinically recurrence was extremely common. In fact, usually by the time the disease was phagocytic response in association with successful immunisation. The phagocytic power of this patient's blood was when he came under treatment for an aggravated localised staphylococcus infection equivalent, as you see in the chart, to less than half that of a normal man. You here see that his power of phagocytic response was by the agency of successive inoculations of a staphylococcus vaccine augmented till it was equivalent to nearly three times that of a normal man.

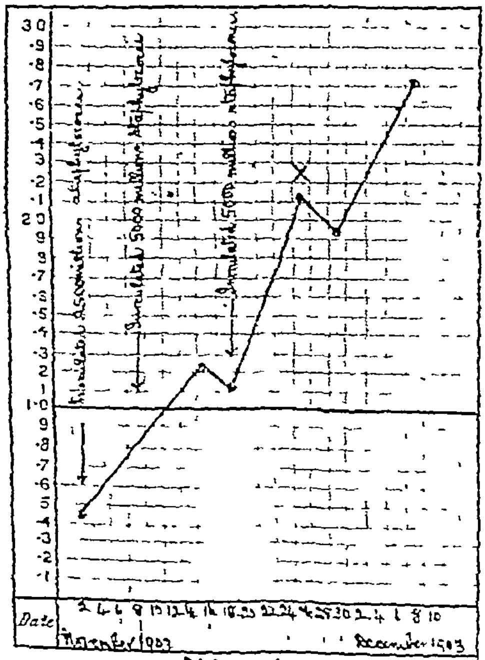

Fig. 1.

Immunisation-chart of a case of staphylococci sycosis treated by inoculations of a staphylococcus vaccine.

At the point which is indicated by an *x* upon the chart—and the clinical condition of the patient had by this time improved in a marvellous manner—an investigation was set on foot with a view to determine whether the increased phagocytic response which had been achieved was referable to an increased power of spontaneous phagocytosis on the part of the white corpuscles, or to an increased opsonic power in the blood fluids. In order to decide between these two alternatives a duplicate series of tests was instituted. In the experiments of Series I. washed corpuscles prepared from the patient were tested (*a*) in association with his own serum and (*b*) in association with the serum of the normal man who served a control. In the experiments of Series II. the washed blood corpuscles of the normal man who served as a control were tested (*a*) in association with the immunised patient's serum and (*b*) in association with his own serum. In each case the technique was that which I have elsewhere described, the same amount of the same staphylococcus suspension being in each case introduced into the mixture of corpuscles and serum. The phagocytic counts which were obtained under these circumstances were as follows:—

	Phagocytic count (i.e., average number of microbes ingested by each P.W.B.C.).
Series I.	
(*a*) Washed *corpuscles* of the *immunised patient* employed in association with the *serum* of the *immunised patient* ...	25·7
(*b*) Washed *corpuscles* of the *immunised patient* employed in association with *serum* of the *normal man* who served as control	13·0
Series II.	
(*a*) Washed *corpuscles* of the *normal man* who served as control employed in association with the *serum* of the *immunised patient*	28·2
(*b*) Washed *corpuscles* of the *normal man* who served as control employed in association with the *serum* of the *normal*	13·0

What now do we learn from these phagocytic counts? We learn from a comparison of the phagocytic counts in experiments (*a*) and (*b*) in Series I. that the serum is a factor which profoundly influences phagocytosis. It does not emerge from a comparison of the two phagocytic counts, Series I. (*a*) and (*b*), inasmuch as here in each case the same variety of leucocytes was employed, whether or not the phagocytic count can be influenced by the variety of leucocytes. A comparison of the phagocytic counts (*a*) and (*b*) of Series II. once more shows that phagocytosis is influenced by the variety of serum. And, again, for the same reason as before, a comparison of these two phagocytic counts leaves it unresolved as to whether phagocytosis can be influenced by the variety of leucocytes which is employed.

From consideration of the all but complete identity of the phagocytic counts obtained in Series I. (*a*) with the count obtained in Series II. (*a*), and again from the identity of the phagocytic count obtained in Series I. (*b*) and Series II. (*b*), it clearly emerges that the phagocytic count is uninfluenced by the variety of corpuscles employed. In short, the whole experiment teaches us that the changes which are associated with the acquirement of immunity are changes in the blood fluids and not changes in the white corpuscles. This conclusion, in addition to its theoretical interest, has also, be it remarked, an absolutely fundamental practical importance. It will make it clear that we may take the opsonic index of any blood as an index of the patient's power of phagocytic response.

(To be continued.)

An Address

ON

MEDICAL SCIENCE AND SCHOOL HYGIENE.

Delivered at the Opening of the Section of Physical Education and Training in Personal Hygiene at the International Congress on School Hygiene in the University of London on August 6th, 1907,

BY SIR JOHN W. BYERS, M.A., M.D., M.CH., M.A.O. (HON. CAUSA) R.U.I.,
PRESIDENT OF THE SECTION.

LADIES AND GENTLEMEN,—My first duty is to thank the organising committee of this great International Congress on School Hygiene—the first to be held in the British Empire—for the honour it has conferred upon me in appointing me to preside over one of the sections, and that the important one "Physical Education and Training in Personal Hygiene."

In reference to the subjects to be discussed in this section it would, indeed, be difficult to calculate what the British nation owes to two men who lived about the same period, who were intimate friends, and who each in a very marked way influenced the other in regard to all that is involved in the promotion of health of body and soundness of mind. I refer to Thomas Sydenham, the "Prince of English Physicians," the man who first correctly taught that medicine as a practical science depended upon close and accurate observation, who always advocated as a fundamental principle in its study an appeal to experience, and who achieved such a reputation that the great Dutch physician, Boerhaave, was accustomed to take his hat off whenever he mentioned his name and to style him "Angliae lumen, artis Phoebum, veram Hippocratici viri speciem." I refer also to Sydenham's friend, John Locke, the philosopher, who, largely owing to his sound judgment, exercised enormous influence over Sydenham and taught him the supreme value to a physician of that priceless gift—common sense. It was in no small degree owing to the personal sway of these brilliant men that towards the end of the seventeenth century there gradually took place a change in English thought in the direction of scientific research and the philosophy of common sense.

JOHN LOCKE, THE PIONEER OF SCHOOL HYGIENE.

In his very interesting treatise on "Some Thoughts concerning Education," published in 1693, Locke wrote: "A sound mind in a sound body is a short but full description of a happy state in this world. He that hath these two has little more to wish for, and he that wants either of them will in primary malignant disease of the gall-bladder, which was certainly commoner than used to be thought. Recurrence after incision for biliary calculi is rare.

Mr. G. P. NEWBOLT (Liverpool) thought that for ordinary case of cholecystitis drainage was the best treatment, but the operation to be chosen in any particular case depended partly on what assistance could be obtained for the operation; with comparatively unskilled assistance drainage was the preferable operation.

Mr. BLAND-SUTTON, in reply, pointed out that nearly every speaker had mentioned one or two cases of recurrence of calculi when only drainage had been done, or calculi had been left behind, or had formed on sutures. Sometimes, of course, it might be impossible to remove the gall-bladder, but he felt sure that in all diseases of the gall-bladder, when possible, it should always be removed.

Mr. W. TAYLOR (Dublin) read a paper on

Intestinal Obstruction Based on 30 Cases.

He described the different morbid conditions which caused the obstruction in the 30 cases on which he had operated. He urged the necessity of immediate operation in all cases of intussusception. Injection could reduce only a small percentage of cases of intussusception, and even when the reduction was apparently complete it might still be partly unreduced. If done early the operation was simple and very successful. In all cases of intestinal obstruction it was desirable to wash out the stomach both before and after the laparotomy.

Mr. J. P. L. MUMMERY (London) read a paper on

Lesions of the Sigmoid Flexure as a Cause of Chronic Colitis.

He pointed out that the recent great advances in their knowledge of the diseases of this portion of the bowel depended mainly on the sigmoidoscope. It was important to remember that chronic colitis might be confined to the sigmoid flexure. There were four methods of investigating the condition of the sigmoid flexure; they were: 1. By the sigmoidoscope; for this the lower bowel must be thoroughly emptied; no anæsthetic was required and in skilled hands no pain and even little discomfort were felt; and no damage should be done. 2. Palpation of the abdomen with the patient under an anæsthetic. 3. Examination of the discharges; this method was too little employed at the present time. Two ounces of the fluid stools were sufficient, and a small quantity of formalin should be added. Deutero-albumose might be found in the urine in some cases of ulceration. 4. By laparotomy. Simple inflammation of the sigmoid flexure might be granular, hypertrophic, or ulcerated, but no hard and fast lines could be drawn between these conditions. In some cases ulceration might be present but no pain, the only symptoms being diarrhœa. Of 36 cases in which Mr. Mummery had found definite lesions seven were cases of cancer. The presence or absence of bleeding was of no diagnostic value; mucous casts might sometimes be found. The length of history was of little importance; in one case there had been symptoms for five years. It must not be forgotten that peritoneal adhesions might cause symptoms of chronic colitis. In the treatment of non-malignant colitis rest in bed was of the greatest importance. It was a mistake to give a milk diet; a full generous diet was advisable and especially fat in the form of butter to make the stools soft should be present. Local treatment was important. The fluid was injected when the patient was in the semi-prone position and then he kept the genu-pectoral position as long as possible. A good lotion to start with was a weak solution of sodium bicarbonate and later a 0·5 per cent. solution of argyrol might be employed. At least a pint should be used at each injection, and from time to time it was advisable to examine with the sigmoidoscope to see the progress that was being made. If adhesions were present it was necessary to remove them at once by operation. Sometimes appendicostomy was useful for irrigation. A left inguinal colotomy might be done, but only for acute cases with severe diarrhœa.

Dr. M. G. FOSTER (London) asked whether some morbid condition was always visible when the sigmoid flexure was examined with the sigmoidoscope.

Mr. MAYLARD asked why the condition should be called sigmoiditis if the whole colon might be affected. He believed in washing out the whole colon through an appendicostomy opening after implanting the lower end of the colon in the abdominal wall.

Mr. MUMMERY, in reply, said that in 25 per cent. of the cases nothing abnormal could be seen by the sigmoidoscope. He explained that the sigmoid flexure might be the only part of the colon affected and therefore it might well be called sigmoiditis. In reply to a further question, he said that with the sigmoidoscope it was possible to see as high as a little above the middle of the sigmoid flexure.

Miss L. GARRETT ANDERSON (London) read a paper on

A Case of Sarcoma of the Small Intestine.

The patient was a woman, 48 years of age, and she complained of pain in the lower part of the abdomen, but it had no relation to food. There was occasional vomiting, the bowels were loose, and the patient was losing flesh. The abdominal wall was thin and on one occasion peristalsis had been visible. On palpation a swelling was felt to the left of the middle line immediately above the pubes; it was dull on percussion, but the abdomen elsewhere was resonant. The tumour was in front of the uterus and a probable diagnosis was made of subperitoneal fibroid of the uterus. The patient said that she had felt a lump there for nine years. On Jan. 3rd, 1906, the operation was performed. The abdomen was opened and the tumour was found to lie over the pelvic brim; no adhesions were present and the tumour was found to be in the wall of the small intestine, its lower end being ten inches from the ileo-cæcal valve. The tumour measured five inches in length and three and a half inches in breadth and involved the whole circumference of the bowel. Several enlarged glands were visible in the mesentery. The piece of bowel involved by the tumour was excised, the ends of the bowel were closed, and lateral anastomosis was performed. Some of the enlarged mesenteric glands were excised, but it was not found possible to remove them all. Recovery had been complete and she had gained more than a stone in weight; there was no evidence of recurrence. When the tumour was examined after removal it was seen that no ulceration was present and no constriction. Microscopically, it was found to be a small round-celled sarcoma and probably the glands were affected with the same condition, but it is often impossible to distinguish between inflammatory changes in lymphatic glands and a small round-celled sarcoma. The condition found in this case was rare. Among 21,000 necropsies in Vienna sarcoma of the small intestine was found three times; and three cases were also described in the *Transactions* of the Pathological Society. Obstruction was rare but there was deterioration of the general health. Prognosis was said to be bad, and only one case was recorded where the patient lived for a year after operation. This patient had now survived 18 months, and still seemed to be in good health.

Mr. G. H. EDINGTON (Glasgow) read a paper on

Cervical Cysts.

In one case—that of a boy, aged 13 years—the cyst had very wide relations: it extended upwards to the styloid process and projections from it passed between portions of the submaxillary gland. It was lined by vascular granulation tissue and after it was excised it was followed by the formation of a ranula under the tongue on the same side. Two cases of branchial cyst were also described; in one, a boy, eight months old, the fistula opened near the lower end of the sterno-mastoid, and the cyst was lined partly with ciliated and partly with stratified epithelium; in the other the condition was bilateral and the fistula opened nearly on a level with the upper end of the thyroid cartilage; the cyst was lined with squamous epithelium. In all these cases the internal attachments of the cyst were a much better guide to the origin of the cyst than was the external opening. Most of these cysts arose in connexion with the second branchial cleft; some might result from the persistence of the sinus precervicalis. The best treatment always was to excise, though this was in opposition to the teaching of most of the text-books. The paper was illustrated with some excellent photographs and diagrams.

FRIDAY, AUGUST 2ND.

Mr. MAYLARD read a paper on

The Relative Merits of Transverse, Oblique, and Vertical Incisions in Opening the Abdominal Cavity through the Antero-lateral Region.

Eight years ago Mr. Maylard published in THE LANCET an account of a case of dilatation of the stomach in which he had operated. The abdominal incision was partly vertical and partly transverse. Later a hernial protrusion appeared in the vertical portion of the incision but not in the transverse. In discussing the relative merits of the various city, Belfast, the corporation (through its baths and lodging-house committee) recently made arrangements to admit schoolboys under 12 years of age, when accompanied by a teacher, free to the swimming ponds one day in each week, and it has requested the Commissioners of National Education in Ireland to empower the principals of the primary schools in Belfast to arrange that children attending these schools can avail themselves of these facilities during school hours.

PHYSICAL EXERCISES AND GAMES.

It would be a useless waste of time to discuss which of these plans is the better system of physical culture for children. My own opinion is that a combination of all of them will give the best results, each plan being suited to particular types of pupils and climatic conditions, and it is well to make young people realise that the use of physical exercises will prepare them all the better for being proficient in games and athletics. There can be no doubt that games do not train enough all the muscles of the body and perhaps do not give the same amount of strength as exercises, yet, on the other hand, games (which on medical grounds must not be compulsory on every boy and girl and which should be varied, properly selected, and judiciously supervised) do something more than increase bone and muscle and produce strength. They tend—in addition to bringing about a state of good health—to lay the foundation of mental and moral qualities which were of the greatest importance alike to the individual and to the community, and young people who worked together in the athletic or playing fields learned to "play the game"—that was, to sink their own personal ends or ambitions for the sake of the cricket eleven, or football or hockey team, of which they constituted only a part. In the athletic field a boy was trained to submit to discipline or even self-sacrifice (and sacrifice for a good cause was one of the noblest laws of life), and to obey his captain who was more experienced and had greater skill. The game-playing boy soon saw by the decision of the umpire that there were two ways of looking at a question—the interested or personal, and the scientific or unbiassed. A prig (that is, "a fellow," as George Eliot defines him, "who is always making you a present of his opinions") could not exist in such an environment. He also observed that a player apparently doing little in a distant part of the field often illustrated the truth of the words, "They also serve who only stand and wait," while by and by, if he himself became proficient, he in turn was selected as leader and had to maintain the prestige and position of his school. In such circumstances a boy learned (what was so important for him in the future) not merely to govern himself for the sake of his fellows but also to govern them in turn with tact and without friction. Games, as Mr. Alfred Lyttelton has recently pointed out in his address at Dulwich College, enabled boys to gain a command over their temper, and when played in the true spirit tended to develop such desirable qualities as courtesy and generosity to opponents. It was in this way that those who engaged in games at school gradually became possessed of gifts which must be of countless value in after life in training them to comprehend what was the real meaning and what was the proper object of citizenship, for one of the highest functions of a school was to send out those who had studied within its walls equipped in every respect, so as to be able to render that social service which the State might demand of them—in other words, to be good citizens of the Empire.

While urging the importance of physical education, let me say it must not be overdone either in the case of boys or girls; rather it must be regarded simply as a necessary and useful adjunct to the cultivation of the mind. They heard at present a great outcry against athletics, but it was not the athletics which did the mischief but all the publicity and noise and professionalism (with its attendant evils) associated with them. That gifted parodist, Mr. Owen Seaman, the editor of *Punch*, has well brought out the objectionable features of present-day athletics:—

> "Yet in a hundred scenes, all much the same,
> I know that weekly half a million men
> (Who never actually played the game)
> Hustling like cattle herded in a pen,
> Look on and shout,
> While two and twenty hirelings hack a ball about."

What we want is our boys to play games as recreations, not as means of living, so as to make them better equipped for the struggle of life which is before them.

I believe that if the children of our public schools were instructed in hygiene and temperance and if they were trained by a judicious combination of exercises and games such deplorable exhibitions of athletics as we see in so many of our great cities every week would in time cease to exist. I am confident that our young people—like the boys and girls in the primary schools of Japan who are taught every day the important lesson of civic duties—would learn from being educated together in the principles of hygiene and temperance and in the various methods of physical culture—apart from, and in addition to, their intellectual and mental development—what in later years and in changed circumstances will be of the utmost value—namely, what is the true aim and the proper object of corporate life. They would come to realise that the best kind of education is that which develops all the faculties of mind and body, which cultivates individuality, brings about self-reliance, and forms character, and which makes them feel that the highest type of civilisation is reached by that community in which they can point out the greatest number of examples of men and women who try in every way in their power to better the condition of their less favourably placed fellow-beings. Such an education will make our young people realise the truth of those beautiful lines—

> "So build we up the being that we are,
> Thus drinking in the soul of things,
> We shall be wise perforce; and while inspired
> By choice, and conscious that the will is free,
> Unswerving shall we move, as if impelled
> By strict necessity along the path
> Of order and of good. Whate'er we see,
> Whate'er we feel by agency direct
> Or indirect, shall tend to feed and nurse
> Our faculties, shall fix in calmer seats
> Of moral strength, and raise to loftier heights
> Of love divine, our intellectual soul."

CLEIDO-CRANIAL DYSOSTOSIS.

BY JOHN HILL ABRAM, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL INFIRMARY, LIVERPOOL; LECTURER ON CLINICAL MEDICINE AT THE UNIVERSITY OF LIVERPOOL.

I HAVE had the opportunity of showing at the Liverpool Medical Institution a case of absence of the clavicles. Though not so rare as at one time believed, yet the condition is sufficiently uncommon to justify a record of a fresh case. Villaret and Francoz,[1] reporting a fresh series of four cases in 1905, gave a list of 28 observations up to date, and a further case was reported by Voisin and de Lépinay[2] in February of this year.

Professor A. M. Paterson and Dr. W. H. Broad have been good enough to give me an expert anatomical report on the boy, from which I give the leading points.

Clavicles.—Are almost completely absent on both sides. There is, however, a cartilaginous rudiment on each side, the left being the larger, and articulating with the sterum above the first costo-sternal articulation. The rudiment on the right side is much smaller and immobile. These rudiments and the first ribs are connected with the well-developed coracoid processes by strong fascial bands representing the costo-coracoid membranes. Expansion of the shoulders is accompanied by a tightening of these bands which causes engorgement of the superficial veins of the neck and prevents any abnormal approximation of the vertebral borders of the scapulæ.

Muscles.—The subclavius muscles apparently are wanting, but the platysma, sterno-mastoid, trapezius, deltoid, pectoralis major and minor muscles are well developed. The clavicular fibres of the muscles in question appear to arise from the fibrous membrane described above. The sterno-mastoids possess well-marked tendinous origins which arise close together from the front of the upper end of the sternum, they have an additional origin from the costo-coracoid membrane, and possibly also from the rudimentary clavicles. The trapezius is inserted into the spine of the scapula and into the coracoid process or the fibrous membrane over it; the deltoid muscle has a similar origin. There is an obvious separation of the anterior fibres of the two muscles.

Skull.—Glabello-occipital length, 182 millimetres; transverse diameter, 157 millimetres; horizontal circumference, 555 millimetres; vertical transverse arc, 355 millimetres; naso-alveolar length, 55 millimetres; inter-zygomatic width, 142 millimetres. The skull therefore is markedly brachycephalic, the cephalic index being 86·2. The facial index is 38·7. The fontanelles are persistent; the anterior fontanelle extends along the adjacent sutures backwards and laterally for an inch and forwards along the metopic suture to the root of the nose, forming a crucial groove on the surface of the head. The nasal bones are deficient, sloping downwards and outwards from the middle line and exposing the cartilaginous septum between the lateral cartilages. The mastoid processes are rudimentary and higher than usual in position. The ears are normal. The jaws are small; the palate is narrow and has rather a to femoral hernia, in the 200 bodies examined 58 femoral diverticula were found, 14 of them being bilateral. They occupied exactly the site of a femoral hernia and the diverticula were long and narrow and therefore much more likely to have been the result of traction than of a pushing force from within. As in many cases more than one diverticulum was present there was much probability in favour of a developmental origin. Especially was this the case where the pouches were bilateral. It was impossible that in all these cases herniæ once existed and yet no history of any such lesion was obtainable. The lateral expansion of the pelvis at puberty and the increased pelvic pressure during pregnancy might account for the greater frequency of femoral hernia in women. The results obtained after operating for the cure of femoral hernia supported the view that the presence of the sac was the primary cause of the hernia, for recurrence was rare after operation, even when no attempt had been made to strengthen the abdominal wall at this point. It was difficult to account for the presence of peritoneal diverticula in the femoral region. Mr. Hamilton Russell's explanation was that early in fœtal life, when the bud-like processes appeared from which the lower limbs were developed, a little pouch from the pleuro-peritoneal cavity was produced by the traction of the femoral vessels. In support of this was the fact that in femoral, sciatic, and obturator hernia the sac was close to blood-vessels leaving the abdominal cavity. There was a great practical importance attaching to the saccular theory of hernia, for if the chief factor in the production of the hernia was the presence of the pouch then the mere removal of the pouch would be the chief point in the operation for radical cure.

[2] Bulletin de la Société Médicale des Hôpitaux de Paris, 1905.

Mr. A. HEYGATE VERNON (Bournemouth) read a paper on

A New Operation for Hæmorrhoids.

He had employed the new method for five years and so far as he had been able to learn it was different from any other yet invented. One object in devising the method was to lessen the amount of blood lost. The patient was anæsthetised and placed in the lithotomy position. The anus was gently dilated and then a special conical metal plug was inserted; this was 2¼ inches long and 1 inch in diameter. It had four holes near its lower margin and a large-headed pin was passed through the skin about three-quarters of an inch outside the anus; it passed deep to the external sphincter, into the bowel, then into one hole of the plug and out at the opposite hole, then deep to the sphincter on the opposite side, and so out through the skin. Another pin was passed in a similar manner at right angles to the first. A piece of medium-size rubber-tubing was fixed on the point of one of the pins and then wound round two or three times deep to the pins, and finally was fixed over the point of the pin from which it started. The piles now stood out and with a pair of scissors the piles were cut away. There was practically no hæmorrhage owing to the rubber tubing. This was then taken off and if any bleeding points were present they were tied or crushed. The skin and mucous membrane were then sutured together with a continuous catgut suture, the pins were withdrawn, and the plug was removed. Healing was soon complete. Mr. Vernon had never seen any tendency to contraction. The chief merits claimed for the operation were, the absence of hæmorrhage, the complete removal of all the piles, and the rapid healing of the wound. Mr. Vernon had employed the method with success during an acute attack of hæmorrhoids.

STATE MEDICINE.

FRIDAY, AUGUST 2ND.

Professor T. A. STARKEY (McGill University, Montreal) read a short paper on the

Economical Disposal of Sewage in Small Rural Communities.

He commenced by saying that in this matter it was wise to begin by finding out what that was which the law required from them and the requirements were three in number: (1) that no nuisance should be created; (2) that where sewers did not exist the means for disposal should be such as met with the sanction of the local authority; and (3) that the water-supply should be fully safeguarded. Further, there were three cases which required treatment—the isolated dwelling, small communities of less than about 300 population, and rural communities which more nearly approached to urban conditions. The two common conditions which prevailed originally were the privy pit, which could never be kept clean, which produced a sewage-sodden soil and which could not possibly be disinfected, and the bricked cesspool which required to be emptied at frequent intervals and which was open to many objections in its ordinary form. The method which he recommended and which he had put into force for many years and in many places of such varying climates as Canada and India was a modification of the septic tank with intermittent downward filtration worked on the subsoil irrigation plan. He wished to point out that the separation of excreta from household slops was quite immaterial in the character of the sewage requiring treatment, as had been shown by the analyses which he quoted, and further, that however successful mere tank treatment might be from a chemical point of view, it was only by treatment upon land that a good effluent could be obtained when judged from the standpoint of the bacteriologist. He constructed a covered tank, made watertight with cement or concrete, and capable of holding the sewage produced in 36 hours of the dwellings it supplied; he declined to bind himself as to the quantity of sewage produced per diem, as the consumption of water per head varied so widely in relation to the ease or difficulty of procuring it. After passing through this tank the sewage was passed off in given quantities and at stated intervals by an automatic flushing arrangement into a series of agricultural drains about six inches below the level of the ground. He divided his quantities according to the case and made his automatic flush about every three hours. He saw no objection to the admission of rain-water nor had it given any trouble in the cases within his knowledge. As to the character of the land, of course he admitted some was better than others and no doubt clay was the worst, but he had never found any soil so bad but that it could be worked and utilised. He had in this method followed so far as possible a recent dictum of Professor Bostock Hill which he considered worthy of quotation, in which he said: "Some form of resolution in a tank, followed by oxidation in a filter-bed, is the method which has most claims for adoption at the present time;" and he had the satisfaction by its means of obtaining in practice a really good effluent which would satisfy not only the chemist but the bacteriologist.

Dr. J. SCOTT TEW (West Kent Combined Districts) regretted that his experience of similar conditions had not been so satisfactory as the experiences related by Professor Starkey. He thought, so far as his experience went, that with such a system as had been described a detritus tank would be necessary, and if that were the case the admission of storm water would be fatal to its good working.

Professor H. R. KENWOOD (London) felt grave doubts as to the period of 36 hours for the collection of sewage; it had been found that from 12 to 15 hours was as much as could be safely treated. Where the sewage remained in the tank for so long a period there was a danger that it would become over-septicised and a consequent deposition of colloid matter would take place which would render the working of the tank very ineffective.

Mr. S. N. SCOTT (Plymstock) said that the whole crux of the treatment of sewage in his district was the difficulty of acquiring land, especially in such parts of the rural district as were suburban and might be expected hereafter to become residential; in such places directly land was inquired for for this purpose the price became prohibitive. Houses were unfortunately allowed by the by-laws to be erected without any land attached to them and he could quite understand that if every house stood on half an acre, each individual house could make use of Professor Starkey's system.

Mr. H. H. TIDSWELL (Torquay) related his experiences in Persia where the inhabitants adopted a dry earth system, subsequently drying the mixture in the desert and using it as manure; he found it quite free from nuisance.

Professor STARKEY briefly replied and pointed out that he allowed for a 36 hours' maximum which he found necessary for a 24 hours' flow as it was not wise to estimate too closely to a maximum requirement.

Mr. TIDSWELL then read a paper

On the Influence of the Tobacco Habit on the Health of the Individual and the Nation.

Tobacco, he said, as all were aware, was a poisonous herb containing a virulent poison called nicotine, which was especially injurious to the young. The only use he could conceive for tobacco was to keep off mosquitoes and that was an unimportant matter in this country. Habit was quite as strong a factor in smoking as sentiment; he was really limit its action to certain parts of the bony skeleton. Cleido-cranial dysostosis is the expression of a general defect with predominance on a certain bone group. In my case, for example, the general growth is stunted, the sternum is abnormal, the terminal phalanges in both hands and feet are ill-formed, there are lordosis, coxa vara, and left genu valgum, and it affords support to Couvelaire's theory.

FIG. 4.

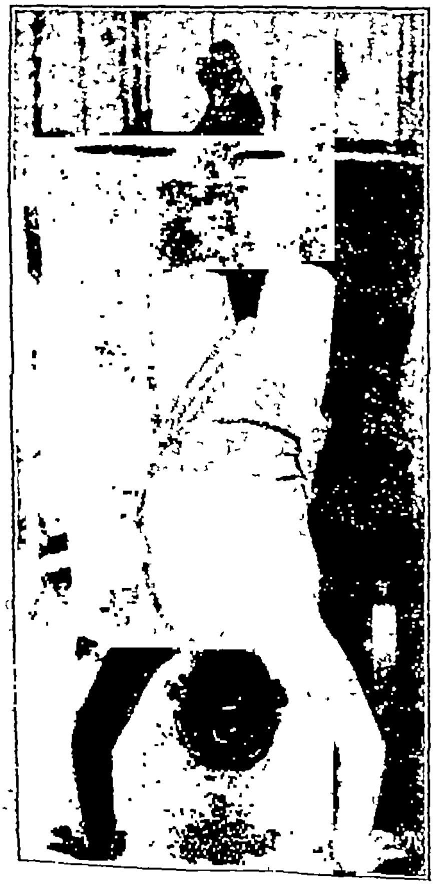

Fig. 4 shows the ability of the boy to stand on his hands.

As I have said, I have been unable to trace any hereditary element in my case. It is important to note, however, that the mother was married at 16 years of age, three months after a severe illness, the nature of which I do not know, which kept her six weeks in bed. She was 17 years of age at the boy's birth, ten months after marriage. The father is a temperate man and I think some weight may be attributed to the mother's illness in the causation of this boy's deformity, especially in view of the general defects and the early period of intra-uterine life at which the ossification of the clavicle begins.

Liverpool.

RAMSEY AND DISTRICT COTTAGE HOSPITAL.—A cottage hospital near Ramsey in the Isle of Man was opened on July 23rd. The portion of the building allotted to patients is of only one storey and consists of four wards, a nurse's room, a linen store, two bath-rooms, and two water-closets. Of the four wards two have one bed each and two have four beds and two cots each. A short corridor connects this portion with a *two-storey block* containing on the ground floor a surgery arranged and fitted as an operating-room, the matron's sitting-room, the kitchen, and various store-rooms. The mortuary is in a detached building not far from the laundry. The flooring of the wards is of polished teak, and elsewhere, except in the matron's sitting-room, the whole of the ground floor is of marble terrazzo. The requisite funds have been provided by the trustees of the Henry Bloom Noble estate.

NOTES ON A CASE OF CARCINOMA OF BOTH OVARIES.

BY M. P. KERRAWALLA, M.D. BRUX., L.M. & S. BOMBAY,
L.R.C.P. & S. EDIN., L.M. IREL.,
RESIDENT MEDICAL OFFICER TO THE BRIGHTON AND HOVE
HOSPITAL FOR WOMEN.

THE patient, a married woman, aged 47 years, was admitted into the Brighton and Hove Hospital for Women on June 20th, 1907, for an abdominal tumour. She had had three children, the last being 20 years ago, and there had been no miscarriages. Her periods had been regular up to three years ago, since when they came on irregularly about once in every six months or so with scanty loss. Her mother had died from cancer of both breasts when 52 years of age, as also had her mother's two sisters. Her own sister was healthy, as also was her own daughter. The present complaint started about 18 months ago with the patient experiencing "dreadful pains" on walking or exertion, arising in the left iliac region and shooting round the back and down the legs as far as the knees. The pains were treated as rheumatic but without giving relief. For several months before admission the patient had developed a slightly yellowish offensive vaginal discharge, which, however, began to assume a pink colour for the last four months before admission to the hospital. She had been several times examined by a well-known London gynæcologist who, however, failed to find anything abnormal prior to the last examination nine weeks before admission, when he noted a hard lump to the right and back of the uterus, though no abdominal swelling was observed. For some time before admission the patient had suffered from a dragging pain during micturition. She had lost weight slightly. Three weeks before being admitted she had for the first time noticed an abdominal swelling, which was then only up to the level of the symphysis pubis. In about ten days more the swelling rose up to about two inches from the umbilicus.

On admission the patient, an intelligent woman, appeared to be well nourished. She had a slight offensive vaginal discharge and suffered from pain in the back and dragging pain on micturition. The abdominal tumour was globular, giving to the touch an impression of irregularity and being quite hard in the left half and fluid in the right. No free fluid could be detected in the peritoneal cavity. Per vaginam the cervix looked and felt healthy. The uterus was fairly mobile and moved with the tumour. A hard irregular lump was felt to the right and back of the uterus. Nothing abnormal could be detected in any other organ of the body.

At the operation the abdomen was opened in the middle line. A large ovarian cyst was discovered and was tapped in the usual manner, letting out about 40 ounces of what looked like ordinary ovarian fluid, which, however, got blood-stained towards the end. The cyst wall was adherent to the posterior surface of the uterus and the left broad ligament and had to be separated, leaving a raw, oozing surface. The inner surface of the cyst wall, especially towards the bottom of it, showed large warty growths. The pedicle was soft and friable; it was torn through in separating the cyst and was secured with difficulty. The greater part of the left broad ligament was tied off and removed. There was a little blood-stained free fluid in the peritoneal cavity which was removed. The uterus felt normal. The right ovary was enlarged to the size of a Tangerine orange and was hard and irregular with papillomatous growths on its surface. It was duly removed; no secondary deposits were discovered. The wound, which was closed in layers, healed by first intention. After the operation the discharge diminished greatly, as also did the pain on micturition. A fortnight afterwards the cervix and the uterus felt normal and freely moveable per vaginam and the patient left the hospital greatly improved.

For the following pathological notes of the case I am indebted to Dr. F. G. Bushnell of the Sussex County Hospital, Brighton:—

The cyst consists of a papillomatous portion and a softer portion of about the consistence of brain matter. The former consists of a dense fibrous stroma which is everywhere invaded by columns of irregularly-shaped carcinoma cells. The soft portion is of exactly similar structure, except that the fibrous tissue is of recent formation. The epithelium is atypical and sometimes multinucleated. Section of the oviduct shows similarly the growth of carcinoma within the lumen. The surface of the cyst shows warty growths. Sections of the ovary of the

Dr. KARL A. GROSSMANN (Liverpool) thought that some of Dr. Landolt's suggestions on the dimensions of instruments must of necessity be modified according to the size of the hand and fingers of the operator; one size would not do for all.

Mr. SIMEON SNELL (Sheffield) read a paper entitled

An Inquiry into the Causes of Blindness in 333 Inmates of the Sheffield School for the Blind,

in which he said that the school housed 70 children. Formerly it took fewer children, and only those who were quite blind, and kept them for a longer period. Since the passing of the Education Act of 1893 the scope of the school had been widened; the partly blind were now admitted—i.e., those who were "too blind to read the ordinary school-books used by children." These cases were, however, few in number and did not affect the scope of that inquiry. The beds were equal in number for males and females, so no information was afforded as to the sexual distribution of blindness. Mr. Snell had always depended on his own examination for a diagnosis and supplemented it by inquiries from parents. In most cases these two lines of inquiry were ample to determine the cause of blindness. In a few, where the clinical signs were indeterminate and where no previous history could be obtained, the cases had been marked unclassified and left out of account. Ophthalmia of the newly born provided the largest number of inmates. Out of a total of 321 cases no fewer than 136 could, with fair accuracy, be traced to the result of this disease. Thus more than a third, or 42·36 per cent., were due to one cause and that a preventable disease. A careful consideration of the records for each year did not point to a diminution of the proportion in recent years. He thought that the medical profession was fully alive to these facts, but that much was needed to be done before midwives could be impressed with the dangers of the disease and the urgent necessity for cleanliness and simple preventive measures. He was pleased to note that recently the Central Midwives Board had censured a midwife for failing to call in medical aid to attend an affected child and that for a like neglect another had been struck off the rolls. Ulceration of the cornea in later years of life accounted for blindness in three boys and four girls. Trachoma accounted for only one case. Interstitial keratitis blinded three boys and seven girls. Sympathetic ophthalmia caused 22 cases, or 6·85 per cent.; of these 14 were boys and eight were girls. The injuries causing these disastrous results were very various: knitting needles, sticks, broken pottery, wire, nails, stones, forks, sparks from fire, the thorn of a tree, scraps of iron, quicklime, caustic potash, and glass were held accountable in one or more cases. And the age at which the accidents occurred were as various, some occurring as early as two years of age and others as late as 14 years. Congenital defects accounted for 47 cases. In three no eyes could be discovered even after careful examination under a general anæsthetic. Large eyes (hydrophthalmia) accounted for five cases. Six cases of microphthalmia with many anomalous conditions of the uvea and lids were almost or quite blind. There was a single case of albinism partially blind and one of nystagmus for which no particular cause could be found. Congenital cataract accounted for 30 cases, or 9·34 per cent.; of these eight were girls and 22 were boys. Several of the cases had been operated upon. In some the operation had been effective so far as the lens was concerned but vision was not improved by reason of a defective optic nerve. Some were likely to have improved vision by further operation and seven had not been operated upon at all, yet from the appearances of ordinary lamellar cataract favourable results might have been anticipated. Amongst these were three brothers; inquiry elicited that the father was similarly affected but five other children of the family were healthy. Retinal, choroidal, and optic nerve disease of congenital nature accounted for 20 cases, or 6·23 per cent.; in some of these a family relationship was ascertained and the children were intellectually dull. A considerable number of the children were blinded by inflammations coincident or subsequent to an attack of one of the exanthemata. Small-pox caused four cases. All were completely blinded; three had not been vaccinated and the fourth had been vaccinated in infancy but suffered from small-pox at the age of 16 years when she was blinded. Scarlet fever accounted for nine cases. In one case there was atrophy of the optic nerve and in the others the actual cause of the blindness was a purulent inflammation of the eye and ulceration of the cornea. Measles caused 11 cases and German measles two cases; in one of these last meningitis succeeded the attack and blindness followed from optic atrophy. Enteric fever was held responsible for two cases of optic atrophy and whooping-cough for another two. Meningitis and brain tumours with optic atrophy accounted for 35 cases, or 10·9 per cent. Injury to the head caused optic atrophy in no less than seven cases. Glioma necessitated the removal of the eyes of two children. There was one case each of compound hypermetropic astigmatism and of high myopia. In one child the eyes were destroyed by burns resulting from a fall into a lime-pit. Malingering accounted for one case—that of a girl, aged 18 years, who was taken from the workhouse infirmary; one eye was amblyopic from squint but the other had excellent vision.

Mr. SYDNEY STEPHENSON (London) commented on the high proportion (42·36 per cent.) of the inmates blinded as the result of that preventable disease—ophthalmia neonatorum. He moved for the acceptance of the meeting the following motion:—

> That in the opinion of the Section of Ophthalmology the time had come when action should be taken by the British Medical Association towards the prevention of ophthalmia neonatorum.

The motion was seconded by Dr. GROSSMANN, who said that at the Birmingham meeting of the Association and at the International Congress at Berlin he had moved similar resolutions, and was carried unanimously.

Dr. ALEXANDER TROTTER (Perth) said that ophthalmia neonatorum was diminishing in his district. He had only seen one case in the general hospital in four years and not one in his private practice. He believed that this was due to the use of silver nitrate as a prophylactic.

Mr. F. RICHARDSON CROSS (Bristol) urged the necessity of the State dealing with ophthalmia neonatorum. In many infants blind from cataract the condition was complicated by abnormal development of the brain or retina. As regards sympathetic ophthalmia, he felt that a wounded eye should be saved where possible; but all should be carefully watched, for it was easy for a child with a wounded eye gradually to acquire sympathetic ophthalmia without observation and thus become blind. There were cases of optic neuritis in young children which suggested tumour; some recovered and others became blind from optic atrophy. He raised the question whether trephining should not be attempted at an early period of the neuritis.

Dr. JOHN HERN (Darlington) said that he had collected statistics of blindness similar to those of Mr. Snell, though not for so large a number of children. In his experience most of the cases of ophthalmia neonatorum occurred in the practice of midwives, and with the increasing numbers of midwives special endeavours should be made to control this disease.

Dr. CECIL E. SHAW (Belfast) supported Mr. Stephenson's proposition. He felt sure that the Science Committee of the Association would gladly take up the matter. He thought that Mr. Stephenson should indicate the form which the proposed action should take. He had noted recently in Belfast some cases of ophthalmia neonatorum caused by the use of too vigorous prophylactic measures employed by midwives.

Dr. W. E. F. THOMSON (Glasgow) said that he had himself examined the statistics of the Glasgow Eye Infirmary and found during the last 15 years no appreciable decline in the number of cases of ophthalmia neonatorum

Dr. E. DYKES BOWER (Gloucester) considered the number of rare congenital deformities in Mr. Snell's list to be unusually large. He expressed his surprise at the proportion in which cases of certain other disorders occurred in the list.

Dr. HENRY MANNING FISH (Chicago) read a paper

On the Relation of Diseases of the Nasal Accessory Sinuses to Optic Neuritis

He said that optic neuritis in connexion with nasal sinus disease had aroused a good deal of attention of late. Many cases had been reported showing how important was the recognition of the seriousness of this chain of cause and effect. Some few observers appeared still to look upon the two lesions as merely coincident. A search of the literature of the subject elicited records of over 100 cases of both primary and secondary optic neuritis with all degrees of visual disturbance, from papillitis with no reduction in vision, to total loss of perception of light. The cases showed that affections of each one of the nasal sinuses—the frontal and maxillary, as well as the ethmoidal and sphenoidal—could cause optic neuritis, and this because direct extension of the inflammation was not always necessary to produce an affection of the malignant. It has been my custom for two or three years in all such cases to perform gastro-enterostomy as speedily as possible. As soon as the lines of suture are complete I ask the anæsthetist to pass a long stomach tube; when this reaches the stomach I direct it through the new opening into the distal limb of the jejunum and then while I am stitching up the abdominal wall 50 ounces of peptonised milk, with one ounce of brandy, are given. The effect is most satisfactory. In one recent case of partial gastrectomy the patient was so ill and emaciated that I was doubtful if she could bear the removal of the pyloric growth. I therefore performed gastro-enterostomy, using the cardiac half of the stomach for the anastomosis. When this was complete the stomach tube was passed through into the jejunum and while I was engaged in removing the stomach a substantial meal of 50 ounces of peptonised milk was allowed to trickle into the jejunum. When this patient returned to bed the continuous rectal administration of saline fluid was begun and 16 pints were given. The first two pints contained glucose also. Eight weeks ago in another case I removed the whole stomach, attaching the jejunum to the œsophagus. Contrary to my usual practice I gave the patient no fluid at all by the mouth for 24 hours. During that time he received nine pints of fluid by the rectum and was perfectly comfortable and free from thirst. During the second period of 24 hours he absorbed six pints introduced into the rectum. His recovery was undoubtedly made more certain and less distressing by his free absorption of the fluid given by the rectum.

Dr. Murphy is of the opinion that in cases of acute peritonitis the fluid causes a reverse current of the lymph in the peritoneal lymphatics, "so that instead of absorption taking place from the peritoneal surface the mouth of the lymphatics pour out fluid, bathing the peritoneum with this free discharge," which escapes then by the tubes; that in fact the peritoneal cavity is flushed out by the fluid. I am doubtful if this view is correct. If an innocuous colouring matter be introduced with the saline solution, the fluid discharge from the abdominal wounds is never stained therewith.

We are, I think, entitled to say of this method that the continuous administration of fluids by the rectum is safe, that it is easily borne by the patients, that it effects a very remarkable change in their appearances and in their prospects of recovery after serious abdominal operations, and that the quantities which can be retained by the patient without discomfort do not throw a strain upon the kidneys which they find difficult to bear.

Leeds.

A NOTE ON HYPOPHARYNGOSCOPY.

BY HAROLD S. BARWELL, M.B. LOND., F.R.C.S. ENG.,
SURGEON FOR DISEASES OF THE THROAT, ST. GEORGE'S HOSPITAL; LARYNGOLOGIST, MOUNT VERNON HOSPITAL FOR CONSUMPTION; CONSULTING SURGEON FOR THROAT AND EAR DISEASES, CRIPPLES' HOME FOR GIRLS.

IN THE LANCET of May 25th, 1907, p. 1421, Dr. P. Tetens Hald of Copenhagen described under the above title a new method, devised by von Eicken[1] in Professor Killian's clinic, for the examination of the hypopharynx, or that part of the pharynx which lies below the aperture of the larynx. This region is especially difficult of examination, for the posterior surfaces of the arytenoids and cricoid plate lie in contact with the posterior pharyngeal wall and are not exposed to view in the laryngeal mirror. It is by no means easy to maintain Killian's tubes in position at this spot; they cause great discomfort unless a general anæsthetic be given, which would have been inadvisable in view of the exhausted condition of the patient whose case is related below, and their use is not without risk in cases of ulceration of this region. As this part of the pharynx is often the seat of important lesions and, especially in women, is frequently the site of an epithelioma, any promising method for its examination becomes of great importance. The following case in which von Eicken's method was successfully employed will, therefore, be of interest.

A woman, aged 39 years, was sent to me at Mount Vernon Hospital on June 6th, 1907, by Dr. F. T. Hebb. She complained of pain on swallowing, which began eight months before and grew steadily worse, so that she had eaten no solid food for three weeks and had hardly swallowed anything, even fluids, for the last four days. She appeared very weak and emaciated, the voice was slightly hoarse, and a gland was just palpable on the left side of the thyroid cartilage. On laryngoscopic examination the left arytenoid was seen to be fixed, greatly swollen, and œdematous, the cords were normal, and no ulceration was visible, but a minute red line could be detected on the pharyngeal wall behind the swollen arytenoid, which suggested the upper end of an ulcer in the hypopharynx (see Fig. 1). Nothing more definite could be seen and, for the reasons mentioned above, the use of Killian's tubes appeared inadvisable. I therefore decided to try von Eicken's method and after thorough cocainisation I passed a stout laryngeal probe, covered with moistened cotton-wool, below the cords and made forward traction on the cricoid. A large ulcer could now be seen to cover the back of the arytenoid and cricoid plate and to extend on to the pharynx; it had a greyish-white base and a red raised margin. Fig. 2 shows how the parts were exposed by pulling forwards the larynx. Although the patient was nervous the manipulation caused her no inconvenience. The most urgent indication being to relieve the dysphagia I clipped out a small piece from the swollen arytenoid and admitted her to St George's Hospital on the following day; the arytenoid swelling diminished much in size and the dysphagia was greatly relieved, so that she could eat the ordinary fish diet after 48 hours. Although the probable diagnosis was epithelioma and no history suggestive of syphilis could be obtained she was given mercury and potassium iodide for a fortnight, at the end of which time the ulceration had slightly extended and the gland in the neck was larger, though the arytenoid remained small and the wound made on it had healed. A small piece was now removed from the edge of the ulcer and under the microscope showed definite epithelioma.

FIG. 1.

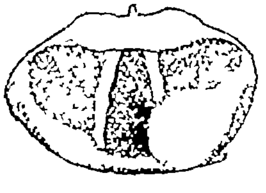

FIG. 2.

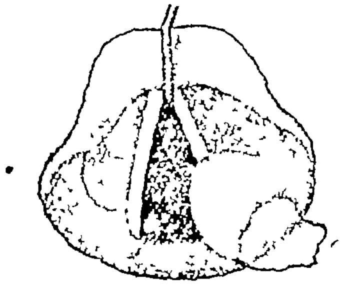

In this case the extensive involvement of the pharynx contra-indicates operation; von Eicken's method has been of great use in showing at once the extent of the pharyngeal involvement and therefore in proving the case to be inoperable. It is also interesting to note how greatly the dysphagia was improved by relieving the tension of the œdematous arytenoid, for the patient was still taking solid food when she left the hospital four weeks after the little operation.

Wimpole-street, W.

---

[1] 1907.

CARDIFF INFIRMARY.—£333 have been received by the treasurer of the Cardiff Infirmary from persons who let the windows of their houses on the occasion of the recent visit of the King to the town.

The observations reported in this paper were principally made on the blood and cerebro-spinal fluid of living persons. The *modus operandi* of the method for obtaining cultures from the blood was then described. Special syringes easily sterilised and kept sterile were used, 10 cubic centimetres of blood were drawn off from the median basilic vein, and this was run into three flasks, each containing 100 cubic centimetres of sterilised broth. These syringes and flasks were always kept ready, and they then waited for the development of a congestive seizure in any of their cases of general paralysis. Blood smears were usually made at the same time, stained with Jenner's stain, and examined microscopically for organisms. In some cases cerebro-spinal fluid was taken by lumbar puncture. The first case examined (Nov. 15th, 1906) was that of a man in the third stage of the disease in a severe convulsive seizure with a temperature of 103° F. A blood count was taken within an hour of the commencement of the seizure and the white blood corpuscles numbered 12,000 per cubic millimetre. There was a polymorph-leucocytosis at the expense of the lymphocytes. Blood smears were taken and stained with Jenner's stain. 10 cubic centimetres of blood were also withdrawn and put into 300 cubic centimetres of broth and incubated. On examining the smears isolated organisms having a bipolar staining like diphtheroids were found in many fields. In one remarkable field, of which a photograph was shown, there were two groups of four and seven bacilli respectively which were well stained and lying quite free. They were unmistakeable micro-organisms. The broth on naked-eye examination after 48 hours appeared to be unchanged and sterile, but on examining a hanging drop organisms were seen in it. Plating was proceeded with in the usual way, but though every effort was made these were all unsuccessful. These repeated failures were disappointing as it was certain that organisms were present. Dr. Theodore Shennan, pathologist to the Royal Edinburgh Infirmary, inoculated mice and guinea-pigs in the laboratory of the Royal College of Physicians in the hope that the micro-organisms might be recovered through them. At the end of four days a mouse was killed and its spleen was found to be enlarged and congested. Two flasks of broth were inoculated from the liver and spleen and both flasks after 48 hours contained a pure growth of bacilli and from each of these plate cultures were made and an organism successfully recovered. A fortnight afterwards another mouse which had been inoculated was killed as it was in a dying condition. It was paralysed on the right side of the body. The other animals inoculated appeared to have suffered no evil effects. On Jan. 6th, 7th, 10th, and 11th blood smears were taken, but no organisms could be detected. On Jan. 13th, when the patient's temperature was 99·8°, cerebro-spinal fluid was drawn off by lumbar puncture and broth inoculated. After 48 hours' incubation the broth appeared sterile to the naked eye, but organisms were seen under the microscope in a hanging drop. Plating was then proceeded with and they were successful in obtaining colonies and in recovering an organism. On the next day the patient's temperature rose to 103 4° and he died. At the post-mortem examination, which presented the typical signs of general paralysis, broth was inoculated from the heart blood and cerebro-spinal fluid after searing the surface of the heart and brain. The former was sterile, but from the broth culture of the latter an organism was recovered. The three organisms which were recovered from this case—namely, from the blood during life, through the intermediary of the mouse, and from the cerebro-spinal fluid during life and after death—were morphologically and culturally identical and they resembled morphologically those seen in the blood films. On 12 other occasions in six cases of undoubted general paralysis an organism was recovered from the blood or cerebro-spinal fluid and owing to alterations in the methods it was not necessary to employ mice in the process of recovering the organism. On the 15 occasions here referred to, in which an organism was recovered, it was found to be diphtheroid, of the xerosis group, and identically the same organism. Its cultural growths and reactions were studied on seven solid and 13 fluid media, the latter in several cases prepared according to different authorities in more than one manner, and they were the same throughout. There was a variability in the reaction in milk litmus alone. Owing to the difficulty of obtaining plate cultures Dr. Muirhead had to improve upon the usual methods, as this organism appeared to be a very feeble grower. In order to be successful another point had to be attended to, and no time was lost after the onset of the congestive seizure in withdrawing the blood. It had been found that leucocytosis developed with great rapidity and in an hour or two the phagocytic action of the leucocytes might destroy all the organisms in the blood stream. The observations of Dr. Ford Robertson and Dr. G. D. McRae had demonstrated this fact experimentally and clinical experience confirmed it generally. The organism found on these 15 occasions was not the original bacillus paralyticans of Dr. Ford Robertson and it was never at any time found. Dr. Ford Robertson had, however, altered his views since October of last year and he now stated that there was another form, which he called the bacillus paralyticus brevis, which was also the cause of the disease. This form was found on one occasion in the cerebro-spinal fluid. It was found post mortem and associated with a streptothrix which was found in pure culture in the heart blood. In this case also the Larbert bacillus (Muirhead's diphtheroid) was obtained in pure culture from both the blood and the cerebro-spinal fluid during life. What pathogenic significance was to be attached to this bacillus? It was most improbable that it was a contamination, considering the varied conditions under which it was obtained and the precautions taken. The majority of the cultures were sterile as no plate cultures were made from them and all the healthy controls were sterile. It was, moreover, the only organism found during life in the blood of undoubted cases of general paralysis and it corresponded morphologically with the organism seen so often in the blood films. All the cultural operations were also performed by a trained and experienced bacteriologist. Was the presence of this bacillus in the blood a terminal invasion or only associated with congestive seizures? It was not the former, as it had been recovered from a patient who was going about at large in good general health though enfeebled in mind. It was undoubtedly most often and most easily obtained during congestive seizures, but as it had been obtained at other times its presence in the blood indicated something more than a relationship to congestive seizures alone. Was it, then, the cause of general paralysis? While it probably played an important part in the symptomatology of general paralysis it could not be asserted that it was the cause. It would appear from these observations that diphtheroid bacilli might possibly play an important part in the symptomatology not only of general paralysis but of other forms of acute insanity as well, and it was possible that this group produced toxins which acted in a special manner on the nervous system.

Dr. F. W. **Mott** read for Dr. J. P. **Candler** (Claybury) an account of

An Investigation into the Incidence of Diphtheroid Organisms in General Paralysis of the Insane,

in the course of which Dr. Candler said that he wished to state the result of a research into the frequency of diphtheroid organisms in general paralysis and other forms of insanity, in which he had been engaged for about one year; but first it was of interest to state that reference to the literature showed that there was hardly any part of the human body where diphtheroid organisms had been obtained by Dr. Ford Robertson in cases of general paralysis from which other observers had not already been able to obtain similar organisms in cases free from any semblance of insanity. His own investigations had comprised: (1) examination of the blood, cerebro-spinal fluid, respiratory, alimentary, and genito-urinary systems of the cadaver; (2) the examination of the urine and urethras during life; and (3) the examination of the blood and cerebro-spinal fluid during life. Briefly the results were as follows. From post-mortem material he obtained diphtheroid bacilli in three out of 25 cases of general paralysis (or 12 per cent.). From cases of insanity other than general paralysis he obtained diphtheroid organisms in four out of 59 cases (or 6·6 per cent.). From the urine of 26 cases of general paralysis examined during life he obtained a diphtheroid bacillus in two (or 7·6 per cent.). From the urine of other cases of insanity he obtained a diphtheroid bacillus once out of 28 cases examined (or 3·5 per cent.). From the urethras of general paralytics he obtained diphtheroid bacilli in five out of 31 cases (or 16 per cent.); from the urethras of other forms of insanity six out of 44 cases (or 13·6 per cent.). The total number of cases examined was 223, of which 82 were cases of general paralysis. The total incidence of diphtheroid bacilli in general paralysis was 12·2 per cent., compared with among scholars in elementary schools but a reliable estimation of the amount of tuberculosis in all its forms and stages among the children of school-going ages in each district under an education authority. There is need also for careful inquiry into the amount of tuberculosis in those attending our higher and secondary schools.

Tuberculosis, more particularly of the lungs, exists among many teachers. During recent years I have examined a considerable number of such cases. In many involvement of the larynx occurs. Dr. J. Tatham has shown that the mortality from consumption among teachers is high in England and Wales. The same seems to be the case for Scotland and Ireland. The experience of Canada and the United States affirms the same. Many teachers certainly continue their work after they have become "open" cases. The presence of a consumptive teacher, placed, it may be, in an insanitary school, and in charge day after day for long periods at a time of debilitated and tuberculously disposed children, is so grave a risk that no education authority should be permitted to accept it. In Denmark every teacher on appointment to a public school is obliged to present a medical certificate not more than three months old, stating that he or she is not affected with any contagious form of tuberculosis of the lungs or larynx. If a teacher is found to be suffering from either of these forms of tuberculosis he or she may be dismissed with a pension of not less than two-thirds of the salary. Medical inspection is necessary for both teachers and scholars not merely to detect disease when well established but so that those predisposed may be recognised and suitably dealt with. Among upwards of 1600 children belonging to the various branches of the Children's Home and Orphanage, of which I am physician and medical adviser, we find that something like 25 per cent. are of consumptive parentage or are to be considered as specially predisposed to tuberculosis. The medical officer of schools will be able to render invaluable service by examining the upper air passages, tonsils, and other channels by which tuberculous infection occurs.

In considering the subject of tuberculosis among children of school age it is very necessary to break loose from all restricting conceptions and to view the school and its scholars from the broadest hygienic standpoint. It should be the duty of both medical officer and teacher to coöperate in defending the child as far as possible from all influences making for tuberculosis. I believe that most of the tuberculosis occurring among children of all ages is home-born and home-grown. Bearing upon this point the remarkable facts recently furnished me by Professor Emmett Holt deserve very serious study. *Professor Holt states:—*

> During the 19 months ending May 1st, 1907, 67 cases of pulmonary tuberculosis have been treated in our New York Babies' Hospital, 62 of these being children under two years and 15 under six months of age. The diagnosis rested upon finding bacilli in the sputum in 54 of the living cases; upon post-mortem examination in ten; and of the remaining three, one had tuberculous meningitis (tubercle bacilli were found in the fluid drawn by lumbar puncture), one reacted to tuberculin, and the third presented typical clinical symptoms of pulmonary tuberculosis. In only half of these cases was any consolidation of the lungs noted at the time the diagnosis was made, and in nine cases there were *no* pulmonary signs whatever, the infants having been admitted for other conditions than tuberculosis.

By adopting a special method for the collection of the sputum from these cases Professor Holt was able to demonstrate the presence of tubercle bacilli in no less *than 80 per* cent. of the cases, and "the possibility of infection at home was known to have existed in at least 40 per cent. of the children." It is very necessary, however, to insist that large numbers of our schools both in rural and urban districts are highly insanitary and rich in conditions predisposing to tuberculosis.

School sanatoriums are badly needed. Tuberculous and tuberculously disposed children should not be sent to a sanatorium dealing with consumptive adults. Consumptive children have special needs. Those in charge should be capable of carrying out the duties both of nurse and teacher. Many a woman as nurse-teacher should find an ideal vocation. When a school child is living in close association with consumptive parents or in an environment definitely tuberculous it might be well if some such method could be adopted as that advocated and so successfully carried out by the late Professor Grancher for Parisian children, whereby tuberculous little ones are removed from their infected and infecting homes and boarded out with healthy foster parents in the country at a comparatively low cost. The forest schools of Germany are accomplishing much and the interesting experiment of the London County Council in this direction will be watched with interest. In many crowded homes in both town and country large numbers of children are slowly dying from consumption and other forms of "open" tuberculosis, thereby perpetuating and multiplying the disease. For advanced and hopeless cases havens of refuge are urgently required. The subject is far-reaching and peculiarly perplexing, and surrounded by what seem to be almost insoluble difficulties. Only by coördination of knowledge and coöperation of effort can we hope to obtain directing principles and secure effective practice.

I believe progress might be considerably expedited if we could form an International Association for the Study, Prevention, and Treatment of Tuberculosis among Children.

Harley-street.

Reviews and Notices of Books.

Chemical Pathology. By H. GIDEON WELLS, Ph.D., M.D., Assistant Professor of Pathology, University of Chicago. London and Philadelphia: W. B. Saunders Company. 1907. *Pp.* 549. *Price* 15*s*. net.

ALTHOUGH pathology has long been regarded as one of the sure foundations of medicine, up to comparatively recent times by this term has been understood pathological anatomy, which represents the results of disease, not the successive steps—chemical, physical, and structural—which ultimately bring about those phenomena which are laid bare in the post-mortem room. Relatively seldom has the pathologist attacked his problem from the chemical point of view and by chemical methods. Biological chemistry has made great progress during the last 20 years and many fragments of information concerning the chemical changes that determine pathological phenomena have accumulated, but they are for the most part scattered through medical, chemical, physiological, and physical literature. The aim of Dr. Wells has been to collect these scattered fragments and to use them for a consideration of general pathology from the standpoint of chemical processes that occur in pathological conditions. The reader must not look for a description of chemical methods. For the benefit of those whose studies in organic and physiological chemistry date back some years an epitome is included of the more modern views concerning the chemistry of the proteid molecule, the composition of the animal cell, and the principles of physical chemistry, in so far as they apply to biological problems. The general consideration of enzymes is written with a similar object (pp. 61–103). The scope of treatment will be best grasped by stating the aspects from which the author sets forth his subject—viz., nature of enzymes and their actions, toxicity, intracellular enzymes, oxidising enzymes, lipase, intracellular proteases, and autolysis. Perhaps the fact is hardly realised that every cell is constantly accomplishing an enormous number of chemical reactions of varied nature at one and the same time—in the liver cell there may be going on a score or more of which we know something. The forces that bring about these chemical reactions reside, we say, in the enzymes, and possess attributes that were formerly conceded to the cell itself. The modern view but shifts the problem to certain constituents of the cell whose nature and manner of action are equally unknown. There are, however, certain essential differences between cells and enzymes, such as the susceptibility to poisons of enzymes and cells. Much new and suggestive work has recently been done on anti-enzymes; thus enzymes injected into animals lead to the appearance of substances in the serum of these animals that antagonise the action of enzymes. The principles involved are quite the same as in immunisation of animals against bacterial toxins or against foreign proteids. A fascinating chapter the teeth, probably did so only in this indirect manner, or given at wrong times or too frequently were very liable to upset digestion. The prevention of dental caries must date from earliest infancy; if 39·8 per cent. of children between two and five years of age had decayed teeth it was evident that the mischief was often present before the school age and no dental inspection of schools could take the place of parental care in preventing this evil. Proper feeding in infancy and the prevention of rickets and of digestive disturbance in early life were of prime importance. The teeth should be cleaned twice daily, especially in the evening, from their earliest appearance. There was a most erroneous idea current that decay of the first teeth was of little importance, whereas it was probably more liable to injure the general health and the physical development than at any other time of life. If parents would take their children regularly to a dentist for inspection two or three times a year, and if dentists would see that decayed first teeth were stopped whenever possible, there would be less ill-health and difficulty of digestion in early childhood and probably also less decay in the permanent teeth.

Mr. EDMUND OWEN said that one of the chief causes of dental disease in children was faulty feeding. It was a most unfortunate thing that at the present time so many mothers were unable or unwilling to suckle their children. In children who had been improperly fed, when at last the teeth came through the gum they were frequently faulty in shape, appearance, and power of resistance. In other words, the child was rickety. The milk teeth being for the most part formed before the child had acquired the rickety taint might come through full of promise, but the teeth of the permanent set only stood a poor chance of reaching histological perfection. Mr. Owen insisted that all advertised sterilised foods were bad for children's teeth, and if a child must be brought up on cow's milk, the milk should not be dealt with in any way likely to destroy that living something which was essential for the well-being of the child. As the child grew up his diet improved, meat-juice, vegetables, and fresh foods were added, and it would no doubt be better for him if the meat was freshly killed and not previously stored for six weeks or more in a frozen condition. Mr. Owen proceeded to draw a lesson from the excellent dentition of old British skulls. The best flour for bread was that made of wheat coarsely ground between the old-fashioned mill-stones. This type of bread was in use in East Anglia when Mr. Owen was a boy; it was made in ovens heated with wood faggots, and the loaves were put on the glowing ashes. Such bread not only had hard good crust but the bread itself was crisp and remained fresh when cut across for many days. This bread produced a proper and healthy physiological stimulus to the jaws, but upon modern bread crust was difficult to find, and children were brought up on paps, and patent foods, and messes evolved in the laboratories and for the benefit of the advertising vendor. The manufacturer of drugs, the mere tradesman, had of late taken upon himself to teach medical men how to prescribe and the vendor of patent foods dictated to the profession and the public how children should be fed, and the profession and the public allowed themselves to be led. The general surgeon met with two specially disastrous effects of dental disease, the more serious being the acute septic inflammation of the periosteum and bone starting from the germs incubated in a carious tooth. Such teeth required removal, the presence of a painful swelling being the indication for extraction. Another serious effect of dental disease was inflammation of the cervical lymphatic glands. Sometimes the lymphoid elements of the glands were able to deal with the bacteria and small harm resulted, but frequently the glands were unequal to the task and an acute suppuration might occur large out of all proportion to the original lesion. Behold how great a matter a little fire kindleth! Prevention of dental disease in children was a better study than its treatment and in Mr. Owen's opinion the so-called "high" civilisation of the present day was accountable for most of their dental troubles.

Mr. J. G. TURNER dealt with the pathology of defective teeth, illustrating the various points by lantern slides. Hypoplasia or imperfect development of teeth was most conspicuous in enamel. The various forms could be conveniently classed according to their origin. Hypoplasia of (*a*) malnutrition, (*b*) inflammatory hypoplasia, (*c*) traumatic, (*d*) congenital syphilitic, and (*e*) congenital. The first was the most common; the enamel once formed was incapable of renewal or repair and the formative cells once injured rarely regained their full functional activity. The teeth bore the impress of the pathological process, the position of the deformity on the tooth corresponding in each to the stage of development at which the pathological change occurred. This form of hypoplasia was therefore symmetrical. The amount of damage to the forming enamel varied in degree, in some instances causing almost complete absence of enamel and in others merely causing a dull white or brownish stain. In these dull patches the fibrous character of the enamel was well seen. In some cases a series of grooves ran across the tooth, apparently corresponding to exacerbations and remissions of the exciting cause. At times a line of pits not fused into grooves was seen. Mr. Turner described the microscopical changes in the teeth and proceeded to say that all sorts of "infant foods" seemed to be causative, and plumpness and tranquility of the baby was no criterion of future healthy teeth. Among the histories of early hypoplasia Mr. Turner had investigated three children who had been breast fed and had all suffered continuously from diarrhœa and in each instance the mother's mouth was very septic. All persons with hypoplasic teeth did not give histories of rachitis and all rickety children did not develop hypoplasic teeth. Still, Mr. Turner was inclined to think there was obvious community in the origin of both rachitis and hypoplasia of the teeth. Hypoplasia due to specific fevers was a special form of the hypoplasia of general nutrition. Inflammatory hypoplasia was frequently asymmetrical and in permanent teeth generally owed its origin to inflammatory processes affecting the temporary tooth which was situated immediately above the affected permanent tooth. The inflammatory process left its mark on the microscopical structure of the affected tooth. Bending and irregularity of the dentine was seen, probably due to inflammatory pressure. So-called mercurial teeth might be a form of generalised inflammation, but it was difficult to realise that mercury was ever given in such doses as to cause the results attributed to it. Traumatic hypoplasia differed from inflammatory hypoplasia but little. Syphilitic hypoplasia was well known, but much smaller and less marked degrees of hypoplasia were suspicious of congenital syphilis. The teeth were frequently small, wanting in contour, although the enamel might have a good finish. He had confirmed Darier's observation of a small boss of enamel projecting from an imperfectly developed crown but having a normal enamel surface. Congenital lesions of temporary teeth had not as yet been met with. Mr. Turner referred to an instance of congenital hypoplasia which he thought was unique; it affected five generations. Dental caries was next considered; it was a disease of early life and newly erupted teeth were more susceptible than older teeth. He thought, despite what had been said to the contrary, that there was no disease in which both cause and prevention were so clearly demonstrated. By clinical observation and experiment stagnation of carbohydrate food had been demonstrated to be the predisposing cause and the acid, mainly lactic, produced by bacteria to be the acting cause. Surgically clean teeth could not decay: no bacteria, no caries; no pabulum, no caries, might well be stated as axiomatic. Various accessory causes no doubt contributed but the main underlying fact remained the same. The more injurious foods were the agglutinative carbohydrates and those containing monosaccharides. The former clung to the teeth, the latter were most easily fermentable. Fine flour and biscuits, unwashed starchy foods, as badly prepared rice, &c., were bad. Practically all hypoplasia and dental caries as well, together with oral sepsis in children, could be referred to faulty and improper food, and the prevention of dental caries in children lay rather in the province of feeding than the actual treatment of the disease when established. Extraction of temporary teeth when it was impossible to render them either painless or aseptic was indicated, and the attempt to save by filling a temporary tooth that was septic was improper; more deleterious effects were produced by retaining such teeth than by their loss. Finally, in public health dental disease takes its place with bad housing, feeding, and clothing as one of the root factors of degeneration.

Dr. EDMUND CAUTLEY (London) attached great importance to hereditary predisposition as a potent cause of malnutrition of teeth and their subsequent liability to decay. The delicate, tuberculous, syphilitic, or alcoholic mother was not liable to have children with sound and well-formed teeth. He alluded to the importance of attention to cleanliness and also to the mutual causation of carious teeth and digestive disturbances.

impervious floors short wastes without traps can be used, delivering into a white glazed channel, which passes into a trap before going through the wall; the waste from this discharges over an external gully. Slop sinks, again, are almost obsolete and generally unnecessary when wash-down closets are used. It is a pity in the chapter on Sewage Disposal that some allusion has not been made to the late Dr. G. V. Poore's dry earth system or to the Liernur system which has lately been coming much to the front for low-level districts. Some of the examples given of insanitary work we hoped were now matters of ancient history. Throughout the author uses the poor plumber as a target for gentle sarcasm, though we venture to suggest that many of the faults here attributed to him were committed by his predecessors. Dr. Reid, however, evidently thinks well of the registered man.

The book contains a vast amount of conscientious work and the subject is ably and comprehensively dealt with. It has a good index and a number of illustrations.

LIBRARY TABLE.

The Book of the League of Mercy. Edited by the Rev. P. H. DITCHFIELD, M.A., F.S.A. London: Bemrose and Sons, Limited. 1907. Pp. 82. Price 5*s*. net.—The publication of an attractively printed *pot-pourri* of stories, verses, and pictures has recently become a recognised method of obtaining funds for various deserving charities; the League of Mercy's album (for that name alone describes it) lies before us and it should find a ready sale amongst the supporters of that excellent organisation over which the Prince and Princess of Wales preside. There are some 50 contributions in the volume and although the excellence of its intention should perhaps free it from the voice of criticism we venture to pick out Canon Beeching's strong little poem, "Fatherhood," and Mr. Herbert Railton's graceful sketch of the Lady Chapel in York Minster as the best out of several good contributions. Mr. Granville Fell has boldly challenged comparison with Blake's wonderful conception in rendering, "When the Morning Stars sang together," but has managed to escape plagiarism in his version. Mr. Austin Dobson contributes a dainty copy of introductory verses and there is considerable variety in the remainder of the book, which we commend to all friends of the League. It has the refreshing grace of a complete absence of advertisements and is admirably produced.

A Manual of Normal Histology and Organography. By CHARLES HILL, M.D., Assistant Professor of Histology and Embryology at the North-Western University Medical School, Chicago, &c. Illustrated. London and Philadelphia: W. B. Saunders Company. 1906. Pp. 463. Price 10*s*. net.—This book is intended for the instruction of elementary students and includes a description of the general anatomy of the various organs along with their histological features. "The fundamental facts in histology have therefore been presented in as clear and concise a manner as possible," while "the figures have been selected with considerable care and ...... are to be studied as critically as the text." We quote from the preface. We do not feel sure that the author really expects his elementary students to be critical of his text and illustrations but at least the reviewer may be excused for being so. Frankly, we do not think that the descriptions in the text are well adapted to the needs of beginners. Clearness and conciseness do not necessarily go together and here compression has in places been carried to a point where it renders the meaning obscure, in order to allow of the inclusion of matter which is quite unnecessary in a book of this kind, such as allusions to pathological conditions and to functions of organs quite apart from their structure. The illustrations are better than the text. Many of them are taken from other works and the selection has been wisely made on the whole. Allusions here and there to comparative anatomy are stimulating and we feel that the author might have written a good book if he had confined himself to histology and embryology, omitting details of gross anatomy and the extraneous matter above mentioned and allowing himself rather more space for adequate description of the remainder of his subject. A useful feature of the book is the attention devoted to the teeth, rendering it valuable to dental students. Some coloured diagrams of the development of the uro-genital system are also commendable. The printing and get-up of the book are good and the price is moderate in view of its profusion of figures.

The American Text-book of Prosthetic Dentistry. By Various Authors. Edited by C. R. TURNER. Third edition, revised and enlarged. With 916 illustrations. London: H. Kimpton. 1907. Pp. 896. Price 26*s*. net.—This volume illustrates in a striking manner the great advances that have been made during recent years in the teaching of prosthetic dentistry. Although the greater portion of the subject-matter is of such a technical character as to interest only those well acquainted with the mechanical side of the practice of dentistry there are, nevertheless, portions of the book well worthy of the attention of the medical practitioner. The first of these is the excellent chapter on the Human Dental Mechanism, its Structure, Functions, and Relations. The author of this section of the book is Mr. C. R. Turner, and he has succeeded in giving the reader a most lucid account of the variations in the shape of and the movements of the temporo-mandibular articulation, and an admirably illustrated description of the changes which take place in the jaws following on the loss of the teeth. Another section of the book of interest to the medical man is that dealing with the mechanical treatment of palatal defects. The book throughout is well illustrated and we have no hesitation in stating that it is far and away the most thorough work on prosthetic dentistry that has been published.

First Lines in Midwifery. By G. ERNEST HERMAN, M.B. Lond., F.R.C.P. Lond., Consulting Obstetric Physician to the London Hospital. With 83 illustrations. New edition. London, Paris, New York, and Melbourne: Cassell and Co. 1907. Pp. 222. Price 5*s*.—The number of times this little work has been reprinted since it first appeared in the year 1891 shows how great has been the demand for it and how well it has fulfilled the purpose for which it was written. In this new edition the most interesting change is a supplementary chapter containing the rules of the Central Midwives Board, with explanatory notes by the author interpolated. Midwives should find these of the greatest assistance and their introduction considerably increases the value of the book. Dr. Herman's clear and methodical style of writing is well known and this is one of the best books of its kind, if not the best. It forms a very useful introduction to the study of midwifery for students and a most excellent manual for midwives.

JOURNALS AND MAGAZINES.

The Liverpool Medico-Chirurgical Journal.—The July issue of this journal contains, as usual, many papers of interest. Only a few can be mentioned. A series of observations on cases of Pulmonary Syphilis are recorded in the papers of Dr. John Hay, Dr. R. J. M. Buchanan, and Dr. John Elliott; the diagnosis appears, however, somewhat doubtful in the two instances reported by the last writer. Dr. W. B. Warrington writes on Common Nervous Diseases, pointing out the frequency of disseminated *sclerosis* (contrary to the usual view as to its rarity), the comparatively favourable outlook in some cases of tabes dorsalis owing to the disease becoming stationary, the use of lumbar puncture and of trephining, and many other useful observations. Dr. William Alexander continues his valuable study of Epilepsy

The cases occurring in class (*b*) were as follows: 1. Supraorbital and frontal neuralgia, right-sided, together with photophobia, in a male, aged 30 years, cured by removal of septic bicuspid roots on the right side. 2 Supraorbital and ocular neuralgia with occasional photophobia and amaurosis in a female, aged 32 years, on the right side, cured by removal of septic roots (crowned) of lateral canine and first premolar in the upper jaw. 3. Neuralgia, supraorbital and infraorbital, with swelling of the optic disc following the fixation of a crown on a lateral incisor. The symptoms disappeared when the crown was removed. The patient was a well-known medical man. 4. Infraorbital, supraorbital, and ocular neuralgia with myopia in a male, aged 14 years, cured by treatment of irritated pulps in incisor and molar region. 5. Otalgia accompanied with loss of hearing associated with lower wisdom tooth. 6. Supra-laryngeal and hyoid area neuralgia associated with inflammation and throat pain associated with right lower unerupted third molar. Several other cases of this class were cited, all being associated with some dental pathology and all clearing up when the cause of irritation in the form of a diseased tooth was removed. Catarrhal affections of the antrum (maxillary), tic-douloureux, glaucoma, and iritis were mentioned as occasionally associated with pain referred to the teeth.

Mr. Bennett was inclined to the opinion that most of these cases of eye changes associated with pathological dental conditions were due either to toxic disturbances from the local focus of infection or to spread of infection by continuity of tissue.

Mr. Goadby mentioned a case of antral suppuration in which the optic disc was distinctly swollen and which disappeared on the treatment of the suppuration.

Mr. Colyer remarked that he did not regard the evidence in many of the cases as sufficient to warrant the application of the term reflex; they were in all probability due to toxic or septic origin, particularly one case mentioned in which a muddiness of the iris was observed.

Mr. Turner said the neuralgia of edentulous jaws was the same as the neuralgia or pain of septic osteitis. The swelling of neuralgia which occurred in bad and persistent cases might occur in the parts to which the neuralgia was referred. There might be an analogy to change of colour in the iris or to deafness, due, perhaps, to reflex hyperæmia of the middle ear.

Mr. Coleman said the relation of carious teeth to myopia was very difficult to decipher, but pain in the ear related to carious lower molars might have a developmental significance owing to the segmental development of the fifth nerve.

Dr. Milligan, Mr. Baker, and Mr. Russell Barrett also discussed the cases.

Mr. Ackland in his reply thought that a toxic origin hardly explained Case 3, where the symptoms disappeared in half an hour after the tooth was removed. The swelling of neuralgia was possibly caused by sympathetic vaso-dilatation.

Mr. Baker read a paper on

Difficult Eruption of the Third Molar.

Difficult eruption of the third molar, especially in the lower jaw, was constantly brought to the notice of surgeons and dental surgeons, and the present ideas on etiology and treatment were largely based upon the work of the late Mr. Salter. This observer pointed to disproportion in the size of the teeth and the jaws that held them as not only producing irregularity of the teeth in the front of the mouth but often so little space was allowed for the last molar, that its advent was postponed or prevented for a long period. The irritation and infiltration of the soft parts producing trismus were generally due to the nipping of the soft tissues by the oncoming crown against either the coronoid process or another tooth. That the above hypotheses comprise a large number of cases Mr. Baker was prepared to admit, but there were still a number of instances in which too much importance would seem to be attached to overcrowding and pressure in the production of pain. Precise knowledge as to the causes which impel the tooth to the surface would probably modify their ideas on the subject. Mr. Baker then proceeded to cite two instances in which pain and difficulty to close the mouth were associated with the non-eruption of third lower molars in normal position and without the complication of crowding. In one case the third molar remained in the region of the socket of the second molar for ten years, all the time keeping up general irritation. In the second case the eruption of a third molar in a male, aged 20 years, was attended with acute paroxysmal pain, referred to the usual neuralgic foci. Both first and second molars had been previously removed, so there was no crowding to prevent the eruption of the teeth. Subsequently, as the pain did not subside the lower third molar was removed and the pain, especially that of the inferior division of the fifth nerve, disappeared for a month but then returned. The pain continued with varying intensity until the upper third molar cut the gum. Mr. Baker was inclined therefore to regard the usual text-book statement that the neuralgias arising from the eruption of third molars were due to the difficulties caused by crowding was not a sufficient explanation, as in both the cases recorded no opposition to the eruption of the tooth causing the neuralgia was in operation and yet the pain was intense and only relieved by the extraction of the offending tooth.

Mr. Colyer was in complete agreement with Mr. Baker. He referred to specimens of malposition of the third molar in the museum of the Royal Society of Medicine (Odontological Section): one in a gorilla with the supernumerary third molars in the ascending ramus of the jaw, the other a third molar situated in the sigmoid notch in the human subject.

Mr. J. H. Gibbs (Edinburgh) was much interested in the paper and agreed with Mr. Baker that crowding and insufficient room for eruption were insufficient to account for the pain in a number of this class of case. The majority of his cases had occurred in women.

Mr. Payne mentioned a case in which eruption of a third molar in the mandible of an elderly patient caused acute pain, local and referred. The root of the tooth was implanted in the ascending ramus of the jaw and the crown was entirely covered by gum. It was important to note that the eruption of the upper third molar was rarely attended with such acute pain as the lower third molar, a fact which might be associated with the freer blood-supply and less compact tissue of the upper as compared with the lower jaw.

Mr. Bennett (London) thought that some of the points he proposed to discuss in his paper on Friday had a distinct bearing upon the question.

DISEASES OF CHILDREN.

Friday, August 2nd.

The proceedings commenced with a discussion on

Lumbar Puncture: its Diagnostic and Therapeutic Value,

which was opened by Dr. E Farquhar Buzzard (London). He said that in the course of the past 16 years the literature relating to this subject had become very extensive as the method was applied to the investigation of various diseases, among which tuberculous meningitis and tabes dorsalis were conspicuous. In regard to the technique of the operation he recommended the use of a needle of the hypodermic type, preferably of platinum, the fluid being allowed to run from its end without suction, aspiration being likely to lead to irritation of nerve-roots. The puncture should be made in the third lumbar interspinous space (on a line with the crests of the ilia) while the patient lay on his right side with the spine flexed, surgical cleanliness being carefully observed. The quantity of fluid removed might be from 15 to 40 cubic centimetres. If it ran too quickly or too much was withdrawn there was danger of cardio-vascular and respiratory disturbance, with headache, nausea, and vomiting. The normal fluid was clear, watery, and colourless, having a low specific gravity and containing traces of chlorides, sugar, and serum globulin. It flowed at low pressure, escaping drop by drop. So many minor matters interfered with the correct working of a pressure gauge that he did not think it afforded more trustworthy information than the manner in which the fluid escaped from the open tube. Pathologically the fluid showed variation from this standard in an increase in the amount of albumin and the presence of cellular elements, besides alterations in chemical constitution and the presence of various micro-organisms. These occurred mainly in diseases of the nerve-centres, but in uræmia there were found to be diminution of chlorides, increase in sulphates and phosphates, and also of albumin and the presence of urea. In diabetes there was increase in the quantity of sugar and where katabolic processes in the nervous system were going on cholein was present. In inflammatory conditions a grey

Mackay, decided recently, is one of considerable interest. A complaint was preferred by the corporation of Harrogate under the Waterworks Acts against the respondent, a medical man, to recover the sum of 10*s*., being rent for water supplied by the appellants to and used by the respondent for a motor-car used by him for other than a domestic purpose—namely, for the purposes of his profession or business of a physician and surgeon—during the half-year ending Dec. 25th, 1906. The justices dismissed the complaint but stated a case. Upon the hearing of the said complaint the following facts were admitted or proved in evidence: 1. During the half-year ending Dec. 25th, 1906, the respondent kept a motor-car which he used in and for the purpose of his business or profession as a medical man, although he used it from time to time for purposes of pleasure. 2. The respondent during the said period regularly used water from the appellants' pipes for the purpose of washing his motor-car and for other purposes in connexion therewith. 3. The respondent kept his said motor-car in an outbuilding or premises adjoining his dwelling-house, the rateable value of the whole premises, according to the Poor-law valuation list, being £39, and the appellants had charged the respondent and the respondent had paid the appellants the water rate for water supplied for domestic purposes to the said premises the sum of £1 7*s* 4*d*. for the half year ending Dec. 25th, 1906. 4. The appellants, purporting to act under Section 34 of the Harrogate Corporation (Waterworks Transfer) Act, 1897, had charged the respondent, in addition to the said rate of £1 7*s*. 4*d*. for water supplied for domestic purposes for the half year ending Dec. 25th, 1906, a sum of 10*s*. for water supplied and used during the same half year for other than domestic purposes, that is to say, for business purposes—namely, for washing his motor-car and for other purposes in connexion therewith. 5. The appellants had charged the respondent and the respondent had paid the appellants without complaint the like rate and rent for the half-years ending Dec. 25th, 1905, and June 24th, 1906. 6. The demand note delivered by the appellants to the respondent for the half-year ending Dec. 25th, 1906, was worded like the previous demand notes delivered to the respondent for the half-years ending Dec. 25th, 1905, and June 24th, 1906, and which he had paid without complaint. 7. The respondent did not give any notice that he objected to the charge or to pay such charge for water supplied to him in the way of his business or profession for the purpose of washing his motor-car and using water in connexion therewith until Dec. 11th, 1906, when he informed the appellants' rate collector that he objected to pay the charge. The appellants, in pursuance of Section 34 of the Harrogate Corporation (Waterworks Transfer) Act, 1897, where water is used for other than domestic purposes, make a charge in the case of a motor-car of £1 per annum, in the case of horses 5*s*. each per annum, and in the case of the washing of four-wheeled carriages 7*s*. 6*d*. each per annum, and of two-wheeled carriages 5*s*. each per annum. Under Section 30 of the same Act "the corporation shall not be bound to supply with water otherwise than by measure any building used by an occupier as a dwelling house whereof any part is used by the same occupier for any trade or manufacturing purposes for which water is required"; and Section 34 of the same Act enacts: "The corporation may supply water for other than domestic purposes on such terms and conditions as the corporation think fit, and may supply water by measure either for domestic or other purposes." Section 12 of the Waterworks Clauses Act, 1863, enacts: "A supply of water for domestic purposes shall not include a supply of water for cattle or for horses or for washing carriages where such horses or carriages are kept for sale or hire, or by a common carrier, or a supply for any trade, manufacture, or business, or for watering gardens, or for fountains, or for any ornamental purposes." For the appellants it was contended the water used by the respondent for the purpose of washing, &c., his motor-car was not used for domestic purposes; that as the motor-car was mainly used by the respondent in the practice of his profession it was used in a business and that water supplied for use on such motor-car was supplied for a business purpose within Section 12 of the Waterworks Clauses Act, 1863, and that the appellants were empowered by virtue of the Harrogate Corporation (Waterworks Transfer) Act, 1897, Section 34, to supply water for other than domestic purposes on such terms and conditions as they thought fit; and, further, that the appellants, having supplied water to the respondent and charged him a rent therefor, which rent the respondent had paid without complaint for two half years, there was an implied contract between the appellants and the respondent that if the appellants supplied water to the respondent and he used the water for washing, &c., his motor-car for the half year immediately following, the half year ending June 24th, 1906, the respondent would pay the appellants the same rent that had been charged to, and paid by, him for the two previous half years. For the respondent it was contended that the supply of water for domestic purposes included the supply of water for a motor-car used by the respondent in the practice of his profession of a physician and surgeon; that the Waterworks Clauses Act, 1863, Section 12, applied only to a supply of water for horses or for washing carriages when such horses or carriages are kept for sale or hire or by a common carrier; that the respondent did not keep his motor-car for sale or hire, and that he was not a common carrier, that all the respondent wanted water for was for washing his motor-car, and did not want water for a business, and that the water-rate charged by the appellants to the respondent for water supplied to him for domestic purposes included the water supplied to, and used by, him for his motor-car. The justices were of opinion that the water used by the respondent for the said motor-car was not water used by him for a business. The Divisional Court held that the justices came to a right decision and dismissed the corporation's appeal.

The Duty of Post-mortem Delivery.

Dr. Wynn Westcott recently held an inquest upon the body of a woman who while in labour had died suddenly from rupture of the uterus before the child had been expelled. The deceased had previously borne 11 children and in none of these cases had she experienced a difficult labour. The post-mortem examination showed that the muscles of the uterus and of the heart had undergone extensive fatty degeneration; the uterus had ruptured from the cervix upwards. Her parturition was being assisted by a certified midwife who, in conformity with the regulations issued by the Central Midwives Board, sent for a medical practitioner as soon as the labour proved itself to be irregular. Upon the arrival of the medical man the woman was already dead. The evidence showed that there was a difference of opinion as to whether the unborn child was living when the medical man first saw the deceased woman; he believing that it also was dead did not proceed to deliver the child from the body of the dead mother. Such a case raises the question whether it is the duty of a medical practitioner to deliver a child whom he finds to be still alive within the uterus of a deceased woman. He may alternatively perform the true Cæsarean section and rapidly allow the infant's respiration to commence, or apply forceps and extract the child in the hope that it may still be living when its mouth and nose reach the open air. The advice usually given is that the decision as to what should be done, if anything, to rescue the child should be left to the husband, or, if he is not available, to his next friend. The husband of the deceased woman, having had all the circumstances of the case put before him, may desire that everything possible should be done and that with all speed in order that he may be granted living issue. Certain legal technicalities arise in this connexion. Thus, there are occasions when a child in order to benefit must be born during the continuance of the wedlock of the parents, that is, for example, during the lifetime of the mother; further, it has been disputed whether a child extracted by the Cæsarean section is really "born" at all; it might, indeed, be said that a living child within a dead woman must already have commenced its separate existence and hence was a person for legal purposes. The question of the necessity of Christian baptism in certain of these contingencies must not be overlooked if the parents are known to hold theological views on this matter.

VACCINATION FEES IN CARDIFF UNION.—The board of guardians of the Cardiff Union has decided to reduce the vaccination fees in Barry and Penarth, both urban districts, to 3*s*. 6*d*., the minimum sum allowable. In the more rural districts the fees are reduced to 4*s*. and in the town of Cardiff the minimum fee of 2*s*. 6*d* is to be paid. The sub-committee, which first considered the question, suggested a fee of 3*s*. for Cardiff but the full board out-voted the proposal by a large majority.

advanced the nation intellectually and socially. They might be roughly divided into two groups, the stable and the unstable. The former were well developed, both physically and mentally, and in good order and proportion; the latter were often physically below the average and showed an irregular or one-sided mental development; these cases needed special care and formed the majority of those usually coming under medical attention. From the point of view of the race, a late maturity seemed to be advantageous, and this pointed to preserving slight beneficial variations rather than large ones; from the point of view of the individual, the later-acquired powers of the race might advantageously appear sooner, but this should be in good order and with uniform development. It appears, on the other hand, that anything in the environment likely to produce artificially a premature development of any function or organ was harmful, particularly so in those cases where there was naturally a tendency to extreme deviation from the average; while a careful discipline and social restraint were needed to save some of the extreme cases from social failure. On the other hand, the judicious guide would give the bright youth of the stable class free play as to his line of study, while preventing him from straying over too wide an area, and at the right moment, when his choice was made, he would endeavour to stir the youth's energies and to fire his enthusiasm to the utmost.

Dr. Leonard G. Guthrie (London) said that as regards the physical side attention was drawn to the accumulation of evidence of intimate functional relationship existing between the pituitary, the thyroid and thymus glands, the cortex of the adrenal glands, and the testes and ovaries. All seemed concerned in some mysterious way with bodily growth and sexual activity. Even the pineal body seemed to have a share. Abnormal conditions suggestive of hyperfunction of one or another of these glands accounted for gigantism and acromegaly, precocious obesity, abnormal strength and muscularity, premature sexual development and hirsuties on the one hand, whilst hypofunction seemed responsible for dwarfism, muscular atrophy, myasthenia, sexual infantilism, and general alopecia. The coincidence of tumour conditions of more than one of these glands and of atrophy of one associated with hypertrophy of another was further proof of mutual interaction between them. The exact relationship was obscure. Perhaps a mutual check action was exerted by all on each other. Tumour conditions of the pituitary body were associated with gigantism in early life and acromegaly in adolescence. Sexual infantilism or impotence and loss of hair accompanied each condition. Tumours of the pineal body had in two cases been present with premature development of the sexual organs and hirsuties. The thymus gland seemed concerned with osseous growth. Its extirpation in young cats and dogs was followed by rickety changes and stunted growth. Its hypertrophy was associated with acromegaly, myasthenia, and lymphatosis. Abnormalities of one or all of the above named glands might be responsible for achondroplasia. Enlargement of the thyroid occurred in pregnancy and might coincide either with precocious puberty and menstruation or with cessation of menses. Thyroidal atrophy was the cause of myxœdema, dwarfism, and sexual infantilism. Extirpation of the thyroid and also castration were followed by enlargement of the pituitary body. Tumours of the suprarenal cortex (hypernephromata), especially if malignant, were accompanied by precocious puberty, hirsuties, and extreme obesity with or without premature development of sexual organs, or by remarkable physical, muscular, or sexual development. In addition to gigantism two distinct classes of precocious physical development were described: (1) the precociously obese type; and (2) the muscular or "infant Hercules" type (Parkes Weber). By precocious obesity was meant the obesity commonly seen in middle-aged men and women and not merely excessive plumpness. The fat was evenly distributed and also existed as pads, humps, and rolls in various parts. Stellate venules and "lineæ gravidarum" were common. The children resembled stout middle-aged persons in miniature. Intelligence as a rule was precocious. Of ten examples of this type seven were female and three male. In six of the female cases hypernephromata was found. In one no glandular tumour of any kind was discovered. In two of the three male subjects hypernephromata were present. In one no post-mortem examination was held. The muscular or infant Hercules type was characterised by remarkable growth of stature and muscular strength without obesity and by precocious puberty with hirsuties and virile condition of the sexual organs. This type seemed to be confined to the male sex, unless certain cases of precocious maternity were analogous. 11 examples of the muscular type were cited. In two of these hypernephromata were discovered after death. In two tumours of the pineal gland were found. In one there was a testicular tumour, removal of which was followed by loss of hair on the face and resumption of child-like appearance. In six no post-mortem examination was recorded. One of the latter (Mr. Hugh Lett's patient) was still alive and aged eight years. Photographs of examples of the obese and muscular types of precocious development were exhibited. Hypernephromata might be attended by true precocious development of the generative organs and hirsuties without obesity. Finally, in females true precocious puberty might be caused by ovarian tumours, removal of which (as in the case of removal of testicular tumours in males) was followed by "reversion" to child-like conditions. The prognosis in all but the latter cases was bad. Giants usually died young. The eldest of the muscular and obese children was 14 years and the youngest 14 months at the time of death. The average duration of life was from five to six years.

Dr. G. A. Sutherland (London) also spoke.

ELECTRO-THERAPEUTICS.

Wednesday, July 31st.

The proceedings were opened by the President, Dr. Lewis Jones (London), who, after paying a generous tribute to Professor Stephane Leduc of Nantes for the excellent work he had done in medical electricity, called upon the latter to read a paper entitled

"*The Ions in Medicine.*"

Professor Leduc, after indicating that electricity for medical purposes and the electrolytic process were first applied in England, pointed out how all electrical applications to the human body were essentially electrolytic processes, and that such applications were attended by the passage of ions, the nature of which depended on the solution used to saturate the absorbent covers of the electrode, or if plain water were used the application resolved itself into an electrolysis of a normal saline solution. The density of the current employed was limited by the caustic action of the electrolytic products on the skin which took place when the current density was high. To overcome this tendency he considered that it was very important to use from 15 to 20 thicknesses of absorbent material well soaked in the electrolytic solution between the electrode—which must be very flexible—and the skin. The electrodes must be carefully adapted to the surface and maintained by even pressure. The indifferent electrode should be moistened by pure water only, so as not to introduce any undesired ion into the current. Among the indications for this form of medication Professor Leduc mentioned neuralgias and also pericarditis where iodine ions were employed. In such cases iodine appeared in the saliva in from 40 to 60 minutes. Professor Leduc concluded his paper by remarking on the moral triumph for medical electricity attained by the inauguration of a section devoted to that subject at the annual meeting of the British Medical Association.

Mr. A. D. Reid (London) read a paper on

The Use of the Cryptoscope in Operations for Renal Calculi,

in which he said that his plan was to use a special form of sterilisable cryptoscope by means of which the kidney was examined after being drawn out through the wound. The position of small calculi was easily seen and they could be removed with very small incisions, rendering the splitting up of the whole kidney unnecessary. Lantern slides were shown of renal calculi where during the removal this plan was adopted. The stones were all small and single and in no case was the incision in the kidney more than three-quarters of an inch in length.

Professor Wertheim Solomonson (Amsterdam) described

The Einthoven Galvanometer.

The essential feature of this instrument is the displacement of a fine wire—through which the current passes—in a strong magnetic field. The instrument is capable of measuring the most minute currents and by suitable arrangements the movements of this wire can be photographed, making a very perfect oscillograph. Professor Solomonson during the course of his

True advance could only be achieved by a systematic study of the morbid anatomy and histology of cases of this type. He indicated the general outlines of the research upon which he was engaged, and briefly referred to some of his results. He differed from Dr. Luff in regard to the relationship of gout to rheumatoid arthritis since in some cases examined microscopically he had found urates in the tissues, and a study of the metabolism of a number of cases had shown that the output of urates was altered. In regard to the first joint attacked, in the female the hands were first involved in 27 per cent. of the cases, in the male in only 7 per cent. In his opinion examination by the x rays afforded the most valuable information and he differentiated three forms of the joint condition found in these cases: first, an infective form in which no changes were observed by the x rays; secondly, an atrophic form which was probably a chronic infective variety; and thirdly, a hypertrophic form in which there was often a deposit of urates.

The PRESIDENT of the Association (Dr. HENRY DAVY) said that there was a misconception about the climate of Devonshire in regard to this disease, which, so far as his experience was concerned, was rare in that county. He attributed the bad reputation which it enjoyed in this respect to the slight gout which was formerly common as a result of the lead poisoning which arose from the manner in which the cider so largely used there was prepared before the present improvement in the methods of preparation. In his opinion, early gout was frequently diagnosed as rheumatoid arthritis. He strongly supported Dr. Strangeways's view that various joint conditions clinically different were included under the general term of rheumatoid arthritis. In illustration, he alluded to the condition of tuberculous rheumatism described by French observers in association with tuberculous disease and maintained that the existing confusion would continue until all these conditions were separated. In regard to the infective origin of the condition he advised that they should not too hurriedly assume such an origin for all cases.

Professor T. McCRAE (Baltimore) agreed with Dr. Luff in regarding rheumatoid arthritis as a more or less distinct clinical entity and was of opinion that the different types described by Dr. Strangeways were different forms or stages of the same disease, and stated that careful examination of the joints in some cases would reveal different forms of the condition in the same patient. He pointed out the similarity to be observed in the anatomical features with those produced by other infective processes of joints, such as gonococcal arthritis and the typhoid spine in spite of their clinical differences. He agreed with Dr. Luff that rheumatic fever and rheumatoid arthritis were entirely different diseases and emphasised the importance of diagnosis, since he regarded it as a reproach to medicine if cases of rheumatoid arthritis were treated for a long time as rheumatism. He maintained that rheumatoid arthritis involving the spine was much more common than was generally recognised, especially a local form involving three or four lumbar vertebræ, which was responsible for many cases of pain in the back and sciatica. He insisted on the importance of the x rays in diagnosis and in regard to treatment advised that the case should be as carefully dieted and treated as one of pulmonary tuberculosis and on similar lines. A scheme should be prepared for the patient to follow, the diet being liberal and nourishment being given between meals if necessary. Energetic local treatment was important and he emphasised the value of the application of the Bier methods for relief of pain both in acute and chronic forms. It was important to make the patients take a personal interest in the treatment of their joints, and by this means considerable improvement had been obtained in some of the poorer patients at Baltimore. He differed from Dr. Strangeways regarding the value of the study of the morbid anatomy and histology of the disease after death, since the necropsy was usually so very remote from the origin of the disease. More useful results were likely to be obtained from the investigation of cases operated upon early in the course of the disease, which was now sometimes done in America. In regard to the mon-articular cases careful examination would usually reveal slight lesions in other joints.

Dr. W. R. GORE (Llandrindod Wells) regarded the origin of the condition as undoubtedly bacterial, probably due to an infection from the gastro-intestinal canal. There was almost always some gastro-intestinal disorder in these cases, and it would seem as if such a condition might lead to gout in one person and to rheumatoid arthritis in another. In regard to diagnosis, the greatest difficulty arose in distinguishing between early gout and rheumatoid arthritis. In his opinion the uric acid craze had done much harm in connexion with this disease. In regard to treatment, this should be systematic and carried out for a long time. It was important to improve digestion and to give nutritious foods; fats and proteids should be given abundantly but fermentable foods should be avoided. The value of treatment at Llandrindod was chiefly due to its beneficial effect upon the digestive processes. In regard to local treatment, electric-light baths and massage were useful. It was also of great assistance to promote sweating, since it was probable that arthritic toxins were excreted by the sweat. He confirmed the views expressed as to the usefulness of Bier's method.

Mr. W. J. MIDELTON (Bournemouth) called attention to the value of the method recommended by Dr. P. W. Latham of counter-irritation to the spine. Mr. Midelton did not believe that the disease was due to a specific micro-organism but thought that pyogenic organisms were at work in all cases and that the condition was very largely a chronic septicæmia. He was surprised that no speaker in that discussion had referred to the effects of the disease upon the central nervous system. He would prefer to call it chronic cerebro-spinal toxæmia. He agreed with Professor McCrae in regard to the value of treatment on the lines adopted in cases of tuberculous disease.

Dr. W. J. TYSON (Folkestone) was of opinion that a great deal might be effected in regard to the prevention of this disease by the regular and systematic daily exercise of all the joints and by careful attention to the ventilation of rooms. He had seen the disease stamped out from a row of cottages where it was previously rife by the cementing of the floors. He was convinced that much might be done in early cases by simple measures.

Dr. PRESTON KING (Bath) had no doubt that there was a real connexion between rheumatoid arthritis and gout, and thought that there were many cases which could justly be called by the old name of "rheumatic gout." It was difficult in some cases to see any clinical differences between cases following gonorrhœal infections and those from other causes such as from suppuration about the teeth or from abscesses elsewhere. He referred to the confusion resulting from the personal factor in observing and recording cases of the disease and looked forward with hopefulness to the results of Dr. Strangeways's work, from the elimination of that factor.

Dr. J. O. SYMES (Bristol) said that rheumatoid arthritis included two distinct varieties of joint condition, one in which the fibrous tissues were alone involved, to which the name of fibro-arthritis was applied, and the other in which the bony structures suffered, called osteo-arthritis, and in his opinion the condition of fibro-arthritis did not pass on into that of osteo-arthritis. In both kinds there were two chief exciting causes—viz., bacterial infection and some metabolic change possibly leading to an auto-intoxication. In regard to the bacteriology, although he had repeatedly looked for it he had never found Bannatyne's bacillus but had found various cocci. He agreed with Dr. King that rheumatoid arthritis might arise from gout. In distinguishing between subacute rheumatism and rheumatoid arthritis he pointed out that in the latter condition there were often a rapid pulse, cold sweats, a low temperature, some pigmentation, and an exaggeration of the reflexes, while the joint affection was often symmetrical in its distribution, and on cytological examination of the fluid withdrawn from the joint the cells were found to be chiefly of the mononuclear type, whereas in rheumatism the polymorphonuclear forms were in excess.

Dr. MICHAEL G. FOSTER (London and San Remo) discussed the influence of climate on the treatment of this disease. He regarded it as of value in the relief of pain and in the improvement of general nutrition. It was impossible to forecast the effects of climate, but within limits the warmer the place the better. In his experience the effect of the Riviera on these cases was by virtue of its sunshine. He agreed with Professor McCrae in regard to treatment of these patients like those with tuberculosis. He recommended a full diet with stout to drink. Drugs were useless except for the relief of pain. Electric baths, passive movements, and massage were useful.

Dr. D. B. LEES (London) was of opinion that there was great need of further analysis or definition, but he thought that after separating all cases definitely due to gout and given at one or more sittings. Similar large doses were given in mycosis fungoides, sarcoma, and epithelioma, and in every case a period of from 14 to 21 days was allowed to elapse before the same area was again irradiated. In some cases of lupus vulgaris the same method was adopted with satisfactory results. In conclusion Dr. Sequeira raised the question of the risk of setting up a condition similar to the dermatitis of x ray workers by the too frequent exposure to small doses of x rays.

Dr. J. DELPRATT HARRIS (Exeter) read a paper on

Statistics relating to Some Cases of Lupus and Rodent Ulcer treated by the X Rays and Zinc Ions.

This paper went to show the superiority of these methods to those formerly in use and how in the great majority of cases they could be depended upon to give a satisfactory result.

Dr. E. REGINALD MORTON (London) read a paper on

The Therapeutic Use of Alternating Currents of Low Frequency.

He contended that in treating atony or degeneration of muscular tissue the ordinary constant current was not sufficiently stimulating, while in that obtained from a coil the fluctuations were too rapid for the degenerated muscle to derive any direct benefit therefrom. While it was admitted that cases sometimes did well with either, better results would be obtained by using a current that embodied the good points of both, and he had found that a sinusoidal current which reversed its direction of flow from two to four times per second was most satisfactory. The periodicity of the current should be adapted to the state of the muscle being treated, and, speaking generally, the more severe the atony or degeneration the more slowly should the reversals of the current take place. Excellent results had been attained in his hands, especially in atonic dyspepsia and other disorders due to atony of the muscular coat of the digestive tract.

Dr. W. IRONSIDE BRUCE (London) read a paper on

Systematic Radiography.

His idea was always to take every part under the same relative position of tube, part, and plate, such position being the one that had been found by experience to give the best view. He showed a very simple couch for attaining this end and he had also prepared an atlas of normal radiographs made in this way.

In the subsequent discussion Mr. SHENTON insisted on the importance of careful screening beforehand, while Dr. Davidson equally insisted on the superiority of the stereoscopic method over any other.

Professor SOLOMONSON'S paper on

The Electro-diagnosis of Oculo-motor Paralysis

was read by Mr. W. DEANE BUTCHER. In this he showed how, under certain conditions, it was possible to obtain a reaction without risk of damage to the eyeball. His method was to place the electrode on the tendon of the muscle in the same way as was done to obtain the longitudinal reaction in a peripheral muscle in a state of degeneration. The idea was useful in the differential diagnosis of central and peripheral lesions and also threw valuable light on the prognosis in some cases.

Mr. F. HOWARD HUMPHRIS (Honolulu) contributed a paper on

The Rationale of Static Currents.

His contention was that static electricity did not receive the amount of attention and use that it deserved. His theories as to the way it produced its effects—polarisation of cell contents, &c.—were ingenious but had not yet been generally accepted, nor was it generally admitted that static electricity could produce the tangible results obtainable by ordinary dynamic currents.

The session concluded by the exhibition of a series of very interesting lantern slides contributed by the PRESIDENT of the section, Dr. G. H. ORTON (London), Mr. SHENTON, and Mr. C. B. C. LYSTER (London).

THE ANNUAL EXHIBITION.

(Concluded from p. 391.)

IV.—SANITARY APPLIANCES.

The exhibits coming under this heading were not very strongly represented, such things as disinfectants, filters, special bath fittings, and sinks falling in this category. A good deal of attention was given to the simple sanitary devices of the Ajax Sanitary Company, Limited, of 22, Ely-place, Holborn-circus, London, E.C. The invention refers to a very simple and successful attempt to do away with unclean traps and fittings. The invention consists of a sliding valve or shutter fitted in a recess at the back of the lavatory basin, forming as it is said a "moveable weir," over the top of which the waste water may run away faster than it can flow into the basin. The result is that not only is the risk of overflow avoided but the shutter may be removed for cleaning purposes. The lavatory basin and bath wastes are often a source of offence which, however, is not possible with the Ajax slide. Messrs. Slack and Brownlow, of Abbey Hey, Gorton, near Manchester, exhibited various forms of the Brownlow germ filter, which consists of hollow cylinders of porous porcelain. Bacteriological experiments have shown that this material prevents the passage of organisms. The filter is adapted for both high and low pressure, while one form consists of a hospital filter with thermometer attached. Thus a supply of sterile water at any temperature may be obtained for surgical requirements. The Sanitas Company, Limited, of Locksley-street, Limehouse, London, E., exhibited a number of sanitary appliances, including the well-known sanitas disinfectants, sanitas formic lamps and fumigators, and sanitas sulphur fumigating candles and drain testers. Amongst the disinfectants were preparations having a carbolic coefficiency respectively of 20, 10, 8, 5, and 2. Close by were the sanitary compounds of Messrs. Jeyes, of 64, Cannon-street, London, E.C. The stall was occupied chiefly with preparations of cyllin which is guaranteed to be at least ten times less toxic than carbolic acid and to have Rideal-Walker coefficients ranging from 10 to 30 according to the organism employed. The exhibit included medical cyllin, soaps, dusting powder, lint, gauze, and cyllin inhalant. Amongst sanitary appliances may be counted the floor polishes of Ronuk, Limited, of Portslade, near Brighton, which are used satisfactorily in the wards of the principal hospitals. It is convenient also to include in this section the interesting exhibit of the Cellular Clothing Company, Limited, of 72 and 73, Fore-street, London, E.C. The Aertex cellular clothing is porous while it is a non-conductor of heat. It follows that while this cloth protects the body from cold it does not interfere with the escape of the exhalations from the skin. Lastly may be mentioned the exhibit of the Sanitary Wood Wool Company, of 14 and 26, Thavies Inn, Holborn-circus, London, E.C. This exhibit included antiseptic wood-wool tissue for the absorption of discharges, wood-wool sheets for accouchement, wood-wool vaccination pad, and a specially absorbent cotton wool.

V.—MINERAL BEVERAGES, &c.

This section contained several exhibits demonstrating the properties of the mineral waters of some of our home watering-places. The corporation of Leamington, for example, furnished a stall on which were photographic illustrations of this spa and its balneological appliances; there were also specimens of Leamington water. The installation at Leamington includes heat and light baths, treatment by high-frequency current, and swimming and Turkish baths. The advantages of the Harrogate waters and of a stay at the place itself were also amply illustrated at the exhibit of the Harrogate corporation. Specimens of the waters were shown at this stall by Messrs. Croydon and Co., of 55, Wigmore-street, London, W., who took the opportunity also of bringing to the attention of medical men their shadowgraph bougies which have been used with conspicuous success for the exploration of the ureters and kidney in renal disease. The advantages of the Buxton thermal mineral waters were explained at a stall under the management of Mr. John Hatton of Buxton. Here could be obtained an account of the climate of Buxton, of the facilities for exercise there, of the up-to-date arrangements provided for bath treatment, x ray treatment, and electropathic methods. An auxiliary at Buxton appears in the form of moor or mud baths, there being an extensive supply of peat in the immediate neighbourhood of the town. The Perrier Company of 45 and 47, Wigmore-street, London, W., presented a well-designed exhibit of bottles in three sizes of Perrier table water. This water is beautifully soft to the palate, is only slightly alkaline and mineralised, while it is free from objectionable excess of carbonic acid gas. In addition to the well-known purgative bitter water Apenta, the Apollinaris Company of 4, Stratford-place, Oxford-street, London, W., exhibited Johannis water and Apollinaris water. It may not be generally known that Apollinaris water contains natural bicarbonate of soda which gives to it the same antacid properties as are presented in the liquor sodæ effervescens which was at one time in the British recognised the opportunity of complete removal had passed. Mr. Bland-Sutton had only once in 15 years felt justified in removing a malignant gall-bladder. It was found to involve the colon and a portion of that was removed: then it was discovered that the duodenum was also affected and part of that was also taken away, but there was some of the disease unavoidably left and the patient died 14 weeks after the operation. In discussing the comparative mortality of cholecystotomy and cholecystectomy it was important to put the cases into three classes: in one class those performed for acute cholecystitis, especially the perforative cases; then in another class those for chronic cholelithiasis; and, lastly, operations for primary malignant disease of the gall-bladder should form a class by themselves. The idea of Mr. Bland-Sutton's paper may be summed up as follows: "The routine treatment of affections of the gall-bladder should be *excision*."

Mr. A. E. Maylard (Glasgow) commenced by denying that the gall-bladder had no function. It had a very definite function, for it stored bile and therefore it was well not to remove it unless there was definite need for doing so. Drainage of the gall-bladder was really very effective in many cases and it was all that was needed. Patients might do well immediately after an operation but the question was, How were they a long time, say some years, after the operation?

Mr. Charters J. Symonds (London) gave a *résumé* of his work on the gall-bladder from November, 1901, to the present time. During this period he had performed 23 cholecystectomies; in five cases he had removed the gall-bladder and also drained the bile-ducts and in 16 cases he had done choledochotomy. In one case there was a biliary fistula for two months but after that it closed; in one other case there was a biliary fistula for nine months with jaundice but this fistula also finally closed and the jaundice disappeared. Four of the patients died, three as the direct effect of the operation; in the other case pneumonia appeared and death occurred three weeks after the operation, but it was not unreasonable to think that death was not due to the operation. The operation of cholecystectomy might be simple as a rule, but sometimes the difficulties were great, and apparently cardiac reflexes might be excited which might lead to a fatal result. In the cases in which the gall-bladder was not excised seven were treated by simple drainage, and in five others by drainage combined with choledochotomy; in two cases cholecyst-duodenostomy was done. Amongst these cases there were two deaths, and in one of these fatal cases malignant growth and calculi were present, and in the other the death was due in part to the length of the operation and in part to the anæsthetic. It was important not to lay down any hard and fast rule that cholecystectomy should always be performed; not only the character of the disease present must be considered but also the condition of the patient. The conditions for which these operations were done were: in 17 cases there were calculi, in three cases calculi and cholecystitis, and in one case there was deep jaundice with calculi; in this latter case he removed the calculi and drained. There were three cases of stricture of the cystic duct; in one case there were adhesions between the gall-bladder and the duodenum; in two cases there was chronic suppuration with calculi; and in one case hydatids were present. In two cases pancreatic growths were present and in three there was acute cholecystitis; in these two sets of cases drainage was performed. One objection to cholecystotomy was said to be the tendency to the recurrence of gall-stones, but it was very doubtful if this often occurred. If the wall of the gall-bladder was thick and white then excision was certainly best, as it was also if no bile but only mucus was present in the gall-bladder. If distension of the gall-bladder was due to the presence of gall-stones in the common duct, when these had been removed then it was well to remove the gall-bladder also, for it would be damaged. If the cystic duct was stenosed then undoubtedly it was better to remove the gall-bladder. In acute cholecystitis it was better to remove the gall-bladder. In one instance, however, though the gall-bladder was soft and black, Mr. Symonds removed a stone but only drained the bladder and packed a tampon round it and recovery followed. The analogy between the appendix and the gall-bladder was only slight, for in the case of the appendix the colon bacillus was very virulent and it was not a frequent cause of cholecystitis. In his opinion, the operation was far more difficult in men than in women and the incision needed was much greater.

Mr. E. Stanmore Bishop (Manchester) thought that in considering the treatment it was necessary to differentiate clearly between three classes of cases: (1) malignant disease; (2) perforation; and (3) gall-stones. He protested against the routine performance of cholecystectomy in every case. Just as it was possible that the appendix might be useful, as in the performance of appendicostomy, so might the gall-bladder be useful, as in draining cases of cholecystitis and cholangitis, or when the common bile-duct was absolutely blocked.

Mr. J. D. Malcolm (London) agreed that in many cases removal of the gall-bladder was best but if gall-stones were found in a fairly healthy gall-bladder it was well to be satisfied with drainage. It was important to remember that gall-stones rarely recurred. He had only seen two cases. In one it was possible that a stone had been overlooked at the first operation; in the other case another surgeon had removed biliary calculi five years before Mr. Malcolm saw it, and then a stone had formed around a stitch. With regard to the question of recurrence, it must not be forgotten that symptoms of calculi might be present though there was no stone. A good rule was that if the gall-bladder was not inflamed it was better to leave it. Sometimes it was a good thing to open and drain and then two or three weeks later cholecystectomy might be done. Of the greatest value were early diagnosis and treatment.

Dr. J. Ward Cousins (Southsea) said that the diagnosis was very difficult. He mentioned a case in which a little child had been ill three days and had been sent into the hospital with a diagnosis of intestinal obstruction. She was moribund and died without an operation. At the necropsy the gall-bladder was found to be full of pus, a recent perforation was present, and general peritonitis had occurred. Dr. Ward Cousins considered that simple drainage was, in many cases, of the greatest benefit, but if recurrence of symptoms occurred cholecystectomy was desirable. In one case he had done a partial excision of the gall-bladder and the patient did very well. As to the function of the gall-bladder, it was no argument to say that we could do without it; that applied to many organs. It probably had a function, though we might not know it.

Mr. Sinclair White (Sheffield) showed a specimen of a biliary calculus which had formed around a suture one and a half years after the first operation. He exhibited a convenient form of glass drainage-tube which he had devised for the thorough drainage of the gall-bladder; one end was enlarged so that a purse-string suture could easily retain it in position and the other was attached to a rubber tube leading to a bottle. Excision of the gall-bladder was decidedly a more serious operation than drainage, and it was often unnecessary. He had collected 158 cases of drainage, and in two there was recurrence, apparently due to stones left behind.

Professor Irving Cameron (Toronto) considered that in gall-bladder surgery there was room for conservatism. He reminded the meeting that 20 or 25 years ago Lawson Tait had advocated removal of the gall-bladder in all diseases of that organ, but it had been recognised that this was not really an advance, and he thought that 20 years hence Mr. Bland-Sutton's suggestions would have met with the same fate. Cholecystectomy was sometimes necessary, but drainage was the better operation in many cases as in cholangitis with pancreatitis. As to fistulæ, they did not occur if the cases were properly treated. The opening should be kept open until the discharge was found to be free from germs, and then the opening was allowed to close. As to the question of function, he thought that the gall-bladder was useful during sleep for storing bile and that removal of it might interfere with it. In one case of cholecystotomy the patient had intense vomiting, so that mouth feeding had to be given up; then rectal feeding was started, but the rectum soon became irritable and that had to be relinquished. Then he fed the patient through the opening into the gall-bladder and the patient recovered.

Professor W. L. Rodman (Philadelphia) wished to add to the indications for cholecystectomy gangrenous cholecystitis and small shrunken gall-bladders when drainage was quite impossible. The most important point in the operation of cholecystectomy was to make sure that the common bile-duct was pervious and that there was no obstruction for the head of the pancreas. There was no doubt that the operation was becoming more frequent; probably it was three times as frequent now as it was five years ago. It should not be the routine treatment, for drainage was simpler; but cholecystectomy should be done in all suppurative cases and

THE LANCET.

LONDON: SATURDAY, AUGUST 17, 1907.

The Housing Congress.

THE International Congress upon Housing has been engaged, apparently in a very sensible and practical way, in endeavours to approach the solution of a problem of vast importance to all large or crowded communities, and of such a kind that the members of the medical profession have special knowledge of its nature and urgency. Whether as practitioners or as moralists we have numerous facilities for observing the degree in which the influence of home may be traced throughout the career of the individual or the history of the race, and we are daily witnesses of its effect alike upon health, upon intelligence, and upon character. In this country there has no doubt been a steadily progressive improvement as regards many objectionable or injurious home influences, but this improvement has to some extent been neutralised by the overcrowding consequent upon two main factors, the absolute increase of population within the limits of territory, and the increasing tendency of that population towards aggregation in great towns. We had occasion, a few weeks ago, to quote the description given by Sir JOHN SIMON in 1849 of the housing of the working classes in the City of London; and, although it is inconceivable that the horrors therein set forth should anywhere be repeated in the England of our own day, it is none the less certain that, in the face of modern tendencies, their re-appearance can only be prevented by constant vigilance on the part of municipal and sanitary authorities. Mr. BURNS, we observe, has lately expressed the opinion that it is essential, as a first step towards the improvement of housing, to increase the earnings of the lower industrial strata of the community and especially of casual or unskilled labour; but in this pronouncement he has, we think, fallen somewhat below his ordinary level of sagacity. A man, be he a labourer or anything else, will spend his earnings mainly in procuring the things which he wishes to have, and as long as the labourer prefers beer to cubic space or to cleanliness, so long will any increase in his resources be devoted to the real object of his desire, rather than to others which are regarded as more excellent by sanitarians or philanthropists. At a not very remote period, when high wages were being earned in the Midland coalfields, it was not uncommon for miners to dine in May upon salmon, followed by ducklings and green peas, although many of them were contentedly living in hovels, and scarcely possessed clothing which a tramp would have picked up in the road. A few years ago, moreover, when a philanthropic society undertook the work of repairing certain tenements in St. Giles's, and of rendering them fit for human habitation, the chief difficulties which they encountered arose from the tendency of the occupiers to tear out gas- and water-pipes from the walls, or to remove door and window fastenings for the purpose of converting them into money, and later, perhaps, into gin.

An exceedingly instructive report recently issued by the Local Government Board is that of Dr. L. W. DARRA MAIR on the sanitary circumstances of the Whickham urban district, with special reference to its housing accommodation generally, and to certain back-to-back houses at Marley Hill in particular. Dr. MAIR reminds us that, according to the standard of the Census Commissioners, "overcrowding" is defined as a condition which exists when tenements are occupied by more than two persons per room (including every bedroom, sitting-room, or other room); and in the Whickham urban district he found the requirements of this definition to be fulfilled in 62 out of 112 one-roomed tenements, in 398 out of 888 two-roomed tenements, in 179 out of 660 three-roomed tenements, and in 59 out of 585 four-roomed. Stated in another way, the facts were that 698 families, comprising 4889 persons, were so housed as to be living more than two in a room. The number of "overcrowded" families was 27 per cent. of the total number of families in the district and the number of "overcrowded" persons was 38 per cent. of the total population, proportions which are not equalled, and are scarcely approached, anywhere in England or Wales save in certain parts of the counties of Durham and Northumberland. This overcrowding in the Whickham district is most remarkable in a number of small back-to-back dwellings at Marley Hill—dwellings occupied by a well-to-do class of miners and containing furniture and belongings which may almost be described as luxurious and are always good and comfortable. In these dwellings there has for many years been a high rate of mortality, which seems to have been disguised under an ingenious manipulation of figures but which Dr. MAIR renders conspicuous. Taking the ten years 1896–1905 the mortality of Marley Hill as a whole has been 13·9, while that of the inhabitants of the back-to-back houses has been 16·0 and that of the remainder of the district 12·6. The infantile mortality in the back-to-back houses has averaged 221 per 1000, against 147 in the rest of the district, and all this notwithstanding that the inhabitants are distinctly of a superior class, that they are not poor, and that the general sanitary conditions are fairly good. The reason of the overcrowding is explained to be that the houses belong to the colliery proprietors and that by virtue of an old local custom they are occupied rent-free by the miners as part of their wages. Men who cannot get a "rent-free" house receive a money allowance in lieu thereof; but the rent they have to pay slightly exceeds the amount of this allowance, and a miner receiving it, as soon as a "free" house which he can claim by seniority falls in, hastens to occupy it, however inadequate it may be to the requirements of his family. It would be impossible to adduce stronger evidence that neither better pay nor the mere general "elevation" of the working classes will impel them to make any sacrifice for the sake of good housing, and that adequate instruction as to the bearings of the question upon their health and comfort is one of the most urgent requirements of the case.

It scarcely falls within our province to consider the various schemes, municipal or private, philanthropic or incisions for opening the abdominal cavity through the antero-lateral region, they must in the first place consider the anatomical disposition of the muscles, aponeuroses, blood-vessels, and lymphatics. The muscles of the lateral portion of the abdominal wall—namely, the two obliques and the transversalis—ended about two or three inches from the middle line in an aponeurosis which split to inclose the rectus muscle. These aponeuroses met in the linea alba. When, therefore, these lateral muscles contracted the lines of greatest force were nearly transverse. Therefore so far as the division of any part of the sheath of the rectus was concerned a cut made transversely was less likely to lead to a gaping wound than one made vertically. With regard to the blood-supply the vessels which coursed in the anterior abdominal parietes were the deep epigastric, the circumflex, iliac, and the superior epigastric. Therefore the margins of a wound made transversely would be more abundantly supplied with arterial blood than those of a median vertical incision. Again, the lymphatics were more abundant in all the other parts of the abdominal wall than in the median line; hence absorption of effused products was better. The conclusion from these anatomical and physiological facts was that transverse and oblique incisions gave firmer and less yielding cicatrices. Clinical experience showed that these theoretical conclusions were correct. To quote one case illustrating the division of both recti sheaths and recti muscles. The patient, who was a woman, 49 years of age, was suffering from a large uterine fibroid. A ten-inch curvilinear incision was made about one and a half inches above the pubes; in order to obtain the requisite amount of room both recti sheaths and muscles were completely divided. The operation was performed on May 6th, 1904. When the patient was seen by Mr. Maylard a few days ago—that was, after an interval of three years and three months—there was not the slightest indication of any giving of the scar. Not only was the likelihood of a sound, non-yielding scar very great with these transverse or curvilinear incisions below the umbilicus, but they gave much readier access to the pelvic organs and also they reduced considerably the time required for the performance of severe operations on the pelvic contents. In cases where a wound became septic (and every practical surgeon knew by experience that, take what precautions he might, his efforts in this direction would sometimes be defeated) the cicatrix might be as sound as that after the healing of a purely aseptic wound. It was quite the exception for a septic median incision to form a sound cicatrix; the result sooner or later was almost invariably a ventral hernia. The reason of this firmness after a septic transverse incision was simply the good arterial blood-supply and the removal by the numerous lymphatics of the exuded material. In favour of the median vertical incision was the rapidity with which the abdomen could be opened; this rapidity was due to the fewness or complete absence of blood-vessels which required tying. If, therefore, time was a serious consideration in the treatment of any abdominal case a median incision should be made; but in all other cases it would be found that a more secure cicatrix, one which would not ultimately lead to ventral hernia, would result from the employment of a transverse, oblique, or curvilinear incision.

Mr. STANMORE BISHOP read a paper on

Anterior Nephropexy.

The present results of the various operations for nephropexy could not be described as satisfactory and a conclusive evidence of this was to be found in the increasing complication of the operations which had been devised. The requirements of a satisfactory operation were that the kidney should be fixed and at the right height so as to prevent any possibility of a kinking of the ureter and blood-vessels. It must not be forgotten that in most cases of the mobile kidney a certain degree of neurasthenia was present. Mr. Bishop discussed the etiology of moveable kidney but did not come to any definite conclusion, though he agreed that the condition was commoner in women than in men and on the right side than on the left, 80 per cent. occurring on the right side. He attributed this greater frequency on the right side to the fact that the suspensory ligament of the colon which was attached to the kidney on the right side tended to pull the kidney down, as it pulled in the opposite direction to the peristalsis, while on the left side, as the peristalsis was in the downward direction, no such action would occur. An anterior incision for suture of the kidney enabled the operator to see exactly the position in which the kidney was placed. After the abdomen was opened the posterior peritoneum over the kidney was divided transversely and then a transverse incision was made through the kidney capsule about one-third of the way from the lower end, a flap of capsule was turned downwards, and the incision in the peritoneum was sewn up. The left forefinger defined the entrance of the ureter into the kidney and immediately below this a handled needle carrying some stout catgut was passed directly backwards, emerging in the loin; this stitch traversed the flap of capsule; the same piece of catgut was again carried backwards with the needle about 1 centimetre or 1½ centimetres below the first. The two ends were later tied in the loin, the knot lying in a small skin incision. A series of such stitches was inserted around the lower end of the kidney. No important structures were liable to be damaged by these stitches. Mr. Bishop had done the operation on ten cases and all were now doing well. The first two relapsed because then he had not recognised the importance of including the capsule in the stitches. In one case there was some suppuration in the loin around some sutures.[1]

Mr. R. W. MURRAY (Liverpool) contributed a paper on

The Saccular Theory of Hernia.

Owing to the limited time at his disposal he confined his remarks to inguinal and femoral herniæ, though he believed that the saccular theory, as it had been called by Mr. R. Hamilton Russell of Melbourne, offered the only satisfactory explanation of non-traumatic abdominal herniæ. There were two distinct theories of the origin of oblique inguinal hernia. The orthodox theory was that when the hernia appeared during infancy or childhood the sac was pre-formed, but if the hernia occurred during adult life the cause was weakness of the abdominal wall and the sac was acquired. The supporters of the saccular theory believed that in all cases of oblique inguinal hernia the sac was pre-formed. In infancy oblique inguinal hernia was very common, and all agreed that it was due to a want of obliteration of the processus vaginalis. Sometimes—i.e., in 18 per cent. of the cases—the cavity of the sac communicated with the cavity of the tunica vaginalis, but in the remainder of the cases the connexion with the tunica vaginalis had been closed. In the adult the common form of sac was exactly similar to that found most commonly in infants. In adults a hernia might become strangulated the first time it appeared, and in some of these cases it communicated with the tunica vaginalis, and then all would agree that the sac was congenital. In other cases, however, the hernia might become strangulated at its first appearance and the sac might be distinct from the tunica vaginalis. Most surgeons would say that in such a case the sac was acquired, but when such a case was submitted to operation a long narrow neck might be found and no extravasation of blood outside the sac or other evidence of sudden formation was seen, so that it was probable that the bowel had descended into a peritoneal diverticulum which had existed at birth. Mr. Murray described a case where he operated on a hernia in a man, aged 28 years, and the sac was indistinguishable from an ordinary hernia, yet the mother subsequently told him that the patient had had a rupture on that side when a baby, and in all probability the bowel had again descended into a sac which it had occupied 28 years before. It was at least probable that many, if not all, of the herniæ which were usually called acquired were really herniæ in congenital sacs. In children simple ligature of the sac was generally sufficient to effect a radical cure of an inguinal hernia, and even in adults a radical cure was often brought about by little more than obliteration of the sac. Mr. Murray now operated on inguinal hernia both in children and in adults in the following way. He laid open the inguinal canal, tied the sac at its neck, and then he united the aponeurosis of the external oblique by overlapping; and the results were very satisfactory. Inguinal hernia was so common that they ought to be able to find in the post-mortem room evidence of the existence of potential herniæ. Dr. Nathan Raw examined 200 consecutive bodies and found potential herniæ in 47 bodies and in these there were 68 diverticula, of which 13 were inguinal, 52 were femoral, and three were umbilical. The size of the opening at the internal ring varied greatly. Mr. Murray considered that when a patent funicular process existed the occurrence of a hernia depended largely on two factors: the size of the opening and the strength of the muscles guarding it. It was Mr. Murray's opinion that in a person born with a completely obliterated processus vaginalis it was impossible for an oblique inguinal hernia to occur. As until the disease has assumed the chronic form that the signs indicative of destruction of the cartilage become evident accompanied with cartilaginous and osteophytic outgrowths. At this stage, too, the grating in the joints and the resulting deformities are characteristic, being evident both to the physician and to the patient. Dr. Luff further drew attention to the existence of Heberden's nodes, which represent the mildest degree of the disease and are found in the chronic form of rheumatoid arthritis. Some of the speakers laid stress on the aid given to diagnosis by the use of the x rays. The necessary apparatus, however, is not available to all practitioners, and hence a conclusion must be arrived at by a consideration of the general and local signs to which we have alluded. The treatment of rheumatoid arthritis differs in many respects from that adopted in rheumatism or gout, hence again the importance of diagnosis presents itself. The diet must be as liberal and good as the patient can digest and animal food may be freely partaken of. Stout or ale may also be given with advantage. The drugs recommended by Dr. Luff are guaiacol and iodide of potassium. Guaiacol is best given in cachets in the form of the carbonate. At first from five to ten grains may be given three times a day and the dose should be increased by one or two grains each week until from 15 to 20 grains are taken in each dose. Dr. Luff insisted on the importance of continuing this treatment for at least 12 months. The beneficial effects of guaiacol may be added to by administering at the same time iodide of potassium, combined with a tonic to counteract its depressing effect. Iodide of iron has also yielded good results in the hands of some observers. The mechanical treatment of rheumatoid arthritis was also duly discussed, some of the speakers having had the advantage of prolonged experience in hydro-therapeutics. Douche-massage when obtainable has yielded good results and so have peat and brine baths. Radiant heat baths have also proved of advantage. When such measures cannot be obtained, however, much relief may be derived from the use of general massage regularly given. Local massage of the joints is not so satisfactory and physical exercises may also be of advantage when properly regulated.

---

[1] Vide THE LANCET, August 3rd, 1907, p. 253.

We have only alluded to certain points which were raised in a discussion the importance of which cannot be well exaggerated, and we trust that the various opinions which were expressed may be of value to those who are engaged in investigating the subject either from a purely clinical point of view or in the laboratory. Dr. F. J. Poynton, whose researches as to the bacteriology of the disease deserve serious attention, referred to the micrococcus which, working with Dr. A. Paine, he had isolated from a joint and by it had produced rheumatoid arthritis in rabbits. The record of this work was published in our columns, but we are not certain that its suggestiveness appealed with sufficient force to our readers. Dr. T. J. P. Strangeways also stated that he was engaged at Cambridge in a research into the pathology and etiology of the disease, which he did not regard as a clinical entity but as a type. His results will be awaited with interest. The elucidation of the etiology of rheumatoid arthritis has not yet been accomplished, but we trust that the efforts that are now being made will be effectual in placing the nature of the disease beyond doubt and so enable the treatment to be carried out on rational lines.

◆

The Health of the Teacher.

When we called attention last week to the recent plethora of congresses dealing with medical and allied subjects which have met in our midst we implied no lack of sympathy with the objects of their labours nor undue scepticism as to the useful results which might accrue. There is, indeed, something to be said for the simultaneous holding of congresses, as it will frequently happen that opinions expressed at one meeting will be confirmed by experiences recorded at another, while it is possible for men of wide interests to attend with the minimum of inconvenience the sessions of several organisations. Our only regret is that while so much material of interest to our readers is available mechanical reasons compel us to be selective in what we publish, and we particularly regret our limitations in the matter of the proceedings at the Congress on School Hygiene, for many of the problems which came before this Congress have been dealt with from time to time in our columns, and we have continually urged upon the public and on the various authorities concerned the vital importance of the hygienic management of our schools. That great good will result from the holding of this meeting in London we cannot doubt, nor can there, unfortunately, be any question that we i England have much leeway to make up in the field of schoo management and organisation. It is melancholy t be told that this country is not only behind the principa nations in Europe, including Russia, but has also bee passed by Chili, Argentina, and Servia, in providing fo such an elementary necessity as medical examination o school children. There are many physical defects whic render a child incapable of profiting by the instructio provided for his normal companions and which may eve cause school discipline to be a source of actual bodil injury; knowing this we cannot doubt that the neglec shown by this country to provide for the medical inspec tion of school children has caused, and is causin serious drawbacks to many of the rising generation citizens who, as they themselves become more instructe in personal hygiene, will look back on their scho experiences as a period of barbarous mismanageme on the physical side, counterbalanced perhaps (and perha not) by intellectual gain. If, as we hope, the Congress ha succeeded in bringing home to thoughtful minds the realit of the existing evils, we shall, indeed, have cause to co gratulate ourselves on results of national importance. perusal of the *résumé* which we give this week of som of the more important events of the Congress will show fro what varying directions the subject of school hygiene has been approached and what a mass of first-hand knowledge has been placed through its means at the disposal of the public.

In applying the laws of health to school affairs a legion of problems arise, sufficient to supply material for the consideration of many conferences. The children's eyes, ears, and teeth, their hours of relaxation and of sleep, their food, and their varying degrees of mental power all demand attention, and it is manifest that all are receiving it. But there is once a moderate smoker and he well remembered the pangs he endured in breaking himself of the habit. If he had not done so he would have become a hypochondriac. Personally he had no faith in legislation and believed that boys instinctively hated tobacco and that if the foolish sentiment were once killed they would have no desire to smoke. He viewed with horror the cigarette habit which had much to his regret reached even the ladies, and which was killing boys by hundreds and thousands. Boys and girls should be induced to take a pledge not to smoke until they were 50 years of age. Medical men had a duty to perform even if it involved some self-sacrifice on their part—a duty to their nation and to the principles of their profession. So much for the danger to the public, but from the point of view of the individual there were diseases innumerable produced by the use of tobacco. Frontal headache, neuralgias, bronchitis, pharyngitis, and palpitation of the heart were matters of common occurrence, while epithelial cancer of the tongue was often due to smoking; angina pectoris and general paralysis of the insane had also been traced to its use. Having regard to the objects of the Association as set forth in memorandum he felt strongly that it was its duty as a body to enter upon a crusade against this deadly evil which was sapping the health of the individual and undermining the vitality of the nation.

Dr. A. DRURY (Halifax) had always understood that tobacco was introduced into England by Sir Walter Raleigh, a native of that fair county in which they were assembled, but it would appear from the leaflets circulated by Mr. Tidswell that it was the direct invention of Satan. So far no case had been made out against the moderate use of tobacco by adults, but he was quite willing to assent to the dangers of juvenile smoking and to assist in its prevention. He regarded tobacco as a disinfectant and a brain sedative and believed that it was a preventive to tuberculosis. There were, of course, many things which were not fit for boys but which men might do with impunity.

Dr. J. C. MCWALTER (Dublin) understood that tobacco had a preventive if not a curative effect on tubercle. He was himself a non-smoker but he began to think what a lot of innocent pleasure he had missed. Among out-patients he had found few suffering from tuberculosis who were smokers. He deprecated the use of cigarettes by the young and especially by young women.

Dr. F. E. WYNNE (Leigh) pointed out that to deny the use of any article because some people made it an abuse was quite irrational. As to the poisonous nature of tobacco, he had known men poisoned by excess in many things, even the eating of beef could be poisonous. He had no belief in an instinctive dislike to tobacco smoke; horses certainly liked it and donkeys also. He had smoked during the whole of his adult life and although no doubt Mr. Tidswell would tell him that by so doing he had shortened it, he was still alive and not yet in a position to argue the point.

Dr. A. NEWSHOLME (Brighton) hoped it would not go forth as a scientific dictum that tobacco was a preventive to tubercle. It was true that the bacillus of tuberculosis could be killed by nicotine, but in such doses that the human being would also be killed. Bars and smoke-rooms were among the chief places in which the tubercle bacilli were harboured and barmen were notoriously prone to pulmonary tuberculosis; that probably arose from the filthy habit of spitting in such places and from the dust arising from the dried sputa.

Dr. E. J. SLADE-KING (Ilfracombe) gave a short address on the Difficulties attending the Isolation of Infectious Cases in Scattered Rural Communities and pointed out that the chief difficulty was to exclude the neighbours. The best way was to isolate the sick child in the house and endeavour to get the other children boarded out at a short distance for a small charge which could be entered in the costs of the rural authority as part of the expenses of disinfection. He related a story of how in a Devon village a young Sunday scholar died from diphtheria and how the whole of the class-mates were permitted to see the body and to kiss the dead child. The horrible epidemic of diphtheria which ensued produced no less than six deaths in that village and had left an impression on the minds of the people which would never be erased. He emphasised the need for small isolation hospitals for the villages.

Dr. MCWALTER spoke briefly on a method of Injecting Dead Bodies with Formalin before Burial as a method of preventing the rapid pollution of the soil by cemeteries which was not open to the same objections as were urged against cremation.

OPHTHALMOLOGY.

WEDNESDAY, JULY 31ST.

The PRESIDENT (Dr. L. H. TOSSWILL of Exeter), in opening the section, extended a warm welcome to all those interested in ophthalmology who had gathered to the meeting of the Association. Some were familiar friends and others, no less welcome, had come very many miles to their meeting. In the West of England Eye Infirmary at Exeter they had, he said, a centre of ophthalmic work of the greatest interest; it was established in the earliest days of the science and counted only four years less in age and antiquity than Moorfields.

Dr. E. LANDOLT (Paris) opened a discussion on

The Form and Manipulation of Instruments used in Ophthalmic Surgery.

He said that their branch of surgery had formerly been but a part of general surgery and many of the instruments retained the form and design of their origin. In eye work the field of the operation was strictly limited and the globe on which the work was done was one of the most mobile of the parts of the body. They might therefore well assert their independence in the design of their instruments. Precision was everything to them. The linear cataract knife was an instrument which in its design and manufacture was a triumph of art. The keen narrow blade and the well-balanced handle made it perfect in a trained hand. In its use the fingers should alone supply the driving and directing force; the wrist, and still more the arm, should be excluded from participating in the movement. Dr. Landolt contrasted the correct mode of handling the knife, the curette, the scalpel, and the keratome. In the use of cutting instruments on either eyeball or eyelids it was essential that the operator should have a secure point of support for the hand. This was properly obtained by balancing the hand on the little finger upon some part of the orbital margin. Most of the cutting instruments were so arranged that this could not be done; the blades were either too long or they were separated from the handle by a lengthy shaft. He showed drawings of instruments in which this defect of design had been overcome. Iridectomy knives, he felt, left much room for improvement; usually the shafts were so long that one was obliged to grip that instead of the handle. He showed a designfor an improved keratome, in which not only was the shaft of reasonable length, but the blade was so shaped as to permit of the readiest penetration of the cornea and also of the widest corneal section. This he obtained by shaping the arrow-headed blade so that the point was of an acute angle and the edges of the broader part formed a gradually increasing angle of divergence. The balance of many eye instruments depended on the material of the handle. Ivory was still the ideal material. It was not too heavy or too light; it was a poor conductor of heat; it was not slippery but gave a delicate hold. It was regrettable that ivory handles did not stand the high temperatures of sterilisation; the defect was rather in the cement than in the ivory. Perhaps this fault could be overcome. Most forceps had defects in that the springs were too strong and the blades too weak; the fingers were fatigued by overcoming the resistance of the former and when some tissue such as the lacrymal sac had to be held firmly the blades buckled inwards and the tissue slipped from the teeth. Further, the teeth of fixation forceps were placed perpendicularly to the blade; it was rarely that they applied the forceps perpendicularly. Usually the forceps made an angle of 45° with the surface upon which they were to act. He had a forceps made with the row of teeth set at an angle of 45° to the blade; the teeth were long and sharp and interlocked when closed. The effect was excellent. Dr. Landolt discussed the manner of holding the various forms of eye scissors and also their pattern and make. Generally he found that they were too long, both in the blades and in the handles, and further that the handles were too slight for some of the usage required of them.

The PRESIDENT of the Section, Lieutenant-Colonel H. HERBERT, I.M.S., and Dr. R. A. REEVE (Toronto) expressed their agreement with the lines of Dr. Landolt's criticisms.

Mr. W. H. H. JESSOP (London) said that the curvilinear keratome was a most useful instrument, particularly in insuring the wide incision necessary in operations for glaucoma. He found the "cross-bill" forceps exceedingly handy in "advancement" cases, when it was particularly necessary to secure a button-hole of the tissues down to the sclera.

on Sept. 24th, a dinner on the 25th, performances at the Royal theatres on the 26th, and a garden party on the 28th. After the conclusion of the Congress on Sept. 29th there will be a visit to Hamburg, where a social meeting will be held in the evening, and Sept. 30th will be spent partly in sightseeing and partly in a reception by the municipality at the Rathaus. The Congress is divided into the following eight sections: (1) hygienic microbiology and parasitology; (2) dietetic hygiene and hygienic physiology; (3) hygiene of childhood and schools; (4) occupational hygiene and the protection of the health of workpeople; (5) the prevention of infectious diseases and the care of the sick; (6) in two subdivisions (*a*) hygiene of dwellings, towns, and water, and (*b*) hygiene of methods of intercommunication and life-saving; (7) military, colonial, and naval hygiene; and (8) demography. The official languages of the congress are English, French, and German. Any person of either sex interested in hygiene or demography may become a member. The membership subscription is £1 (20 marks); relatives of members and students at colleges or universities may also be received as associate or passive members on payment of 10*s*. (10 marks); they may attend the meetings and the visits to places of interest but may not take part in the discussions. These subscriptions must be sent as soon as possible to the general secretary, Dr. Nietner, Berlin 9, W., Eichhornstrasse 9. The Congress has national committees in each of the participating countries. The chairman of the English committee is Sir Shirley F. Murphy, and the honorary secretaries are Professor George H. F. Nuttall, 3, Cranmer-road, Cambridge, and Dr. Paul F. Moline, 42, Walton-street, Chelsea, London, S.W. As the number of visitors promises to be very large the organising committee of the Congress recommends that hotel accommodation should be secured beforehand, and for this purpose the committee has made arrangements by which the Hamburg-Amerika Steamship Company will receive orders sent by members to its tourist office, Berlin, W., Unter den Linden 8. This company will on application send a list of 12 hotels where rooms and breakfast may be obtained at daily rates varying from 4 to 14 marks. A deposit of 10*s*. must be paid and the order must be given by Sept. 16th at latest. We have already mentioned in our issue of July 6th that a ladies' committee has been formed for the purpose of receiving the ladies, both German and foreign, accompanying members.

MOTOR TRAFFIC AND THE POLLUTION OF THE AIR.

As at present constructed the petrol motor is far from being a perfect engine. It may be satisfactory enough from the point of view of locomotion, but it is transparently defective from the point of view of hygiene. Not only does the motor engine at times give off offensive fumes which are easily visible, but it also discharges unseen gases which, though apparently inoffensive, are decidedly poisonous. The perfect combustion of the petrol is hardly ever attained, and amongst the products of incomplete combustion are two deadly gases—carbon monoxide and acetylene. It is not in the interest of the public that these gases should be discharged freely into our streets, and the chauffeur who, through bad engineering, allows his motor to evolve a maximum volume of these gases for each explosion in the engine is just as much a sinner against hygienic demands as is the manufacturer who makes the air vile with filthy black smoke. If no attention is paid to petrol consumption, the engine being set to give its maximum power, the exhaust will contain a considerable amount of poisonous carbon monoxide. If, however, attention be given to the consumption of petrol, so that just the quantity required for so much energy is expended, then the carbon monoxide is reduced to a minimum amount. It is obvious that the first condition most frequently represents the actual state of things, and it follows, now that the streets of London, at all events, are crowded with motor vehicles, including quite a large number of motor omnibuses, that the outpouring of poisonous carbon monoxide must be considerable. It is to be hoped that this pollution will spare the pedestrians from those symptoms of carbon monoxide poisoning which are so well recognised in the poor collier who has been fortunate enough to escape the direct effects of the colliery explosion but who has been compelled to breathe the treacherous after-damp. Even small quantities of carbon monoxide in the air produce a serious disturbance of the health standard, the leading symptoms being headache, loss of power in the limbs, and a state of semi-consciousness as though a narcotic had been taken. In stagnant weather it would not be surprising to find that such symptoms had their origin in the outpourings of motor traffic and we may next have to consider the question of ventilating the streets when natural agencies in the shape of wind fail us. The old pollution due to animal products is rapidly passing away and a fresh sanitary problem is being presented in the new pollution which arises from the imperfect products of combustion of the petrol of motor vehicles. So long as horse traction is the vogue it is difficult to see how pollution due to physiological combustion can be entirely avoided, but with the new system of locomotion which depends upon a perfectly definite process of chemical combustion prevention should surely be easily accomplished.

ABSINTHE.

SEVERAL French medical authorities maintain that habitual drinkers of absinthe exhibit far greater deterioration of both the mental and bodily functions than can be accounted for by the amount of alcohol consumed, and have suggested that the action of Belgium in prohibiting its sale should be followed. The taste for strongly sweetened and aromatic alcoholic drinks is by no means general in this country, although expensive liqueurs of various kinds are in some request in fashionable clubs and at the other end of the social scale "gin and cloves" is said to have had a vogue some years ago among laundry workers. When extra flavouring is desired the ordinary spirit-drinker adds a modicum of some kind of bitters; rum may also be taken with shrub; and there are stories to the effect that Caledonian topers have been known to impart "warmth" to whisky with cayenne pepper. In France absinthe is the favourite liquor of the dram-drinker. Its fatal fascination for the inhabitants of that country, so bountifully supplied with the natural wine of its own vineyards, is hard to explain. Those whose tastes lie in the direction of something stronger would, if they were well advised, drink brandy distilled from wine, for this does not produce the deplorable effects known collectively as *absinthisme*, against which the medical profession of France have for years been warning their countrymen. Absinthe is said to have been introduced into France about 60 years ago by soldiers to whom it had been recommended as a febrifuge during the long war which resulted in the conquest of Algeria. It has, as many of our readers doubtless know, a peculiar yellowish-green colour, a powerful odour, and a very marked aromatic taste in which oil of aniseed seems to prevail. Many formulæ for making it have been given. They generally resolve themselves into one of two processes—namely, either (1) the distillation of alcohol in which the pounded leaves, roots, and flowering tops of various aromatic plants have been macerated, including wormwood (*Artemisia absinthium*), angelica root (*Archangelica officinalis*), sweet [illegible] *anisatum*), flag root (*Acorus calamus*), an optic nerve. Dr. Fish quoted cases recorded by Richet, Fliess, Hajek, and others in support of this view. Acute sinusitis, he said, was most commonly seen in a cold in the head; there were congestion and a feeling of fulness or heaviness, sometimes accompanied with a greenish nasal discharge. It tended to heal spontaneously. Chronic sinusitis might exist for months or years without causing inconvenience, until some exacerbation was produced by an exposure to cold or damp. Dr. Fish gave some details of 36 cases which he had collected and a general summary of the clinical conditions. Pain was not found to be a marked feature of the disease; it could only be considered to be severe in one or two cases. Purulent discharge, usually held to be a classical symptom, was frequently wanting. Nasal congestion or engorgement of the turbinates, both middle and lower, was found to be a regular and most suggestive symptom. Paresis of the external ocular muscles occurred nine times, or in 25 per cent. The three cardinal symptoms of closed sinusitis were dizziness, dull pain, and nasal congestion. He considered that there was evidence to show that many cases of optic neuritis which had hitherto been credited to some unexplained influence of measles, scarlet fever, influenza, and facial erysipelas were really due to sinusitis or empyema of one or other of the sinuses set up by the infective fever. Hajek, Pearce, Wolff, and Weichselbaum had all found these conditions post mortem and so frequently and regularly that the sequence could scarcely be doubted. In a very few cases the symptoms had been mistaken for glaucoma, but the causal relation of sinusitis with the eye symptoms was proved by a complete recovery on draining the cavities. These cases showed how important was the thorough examination of the nose in all cases of optic neuritis and the importance of securing efficient drainage of sinuses in suspected cases. They should not rely on natural drainage, though it had been shown to be sufficient in some cases.

Dr. R. PICKARD (Exeter) stated that he had recently seen a case of double optic neuritis, not retrobulbar, associated with purulent discharge from above the middle turbinals; the vision improved with relief of the nasal symptoms.

Dr. REBER (Philadelphia) felt that the diagnosis of latent accessory sinus disease was extremely difficult and required great skill. He was hardly prepared to admit that it could be the cause of bilateral optic neuritis. He readily assented to its connexion with unilateral neuritis, and not only sinusitis but carious teeth or some other similar local focus of sepsis might produce the neuritis.

Mr. W. J. CHICHELE NOURSE (London), speaking as a rhinologist, expressed his appreciation of the findings of the paper and referred to the work of Ziem of Dantzic on the subject. In all cases of sinus disease he had noted the condition of the eyes but so far had found nothing of importance.

Dr. BOWER entered a plea for the routine examination of the nasal cavities by the ophthalmic surgeon. He had done so for some time with the result that he did not feel that the association of nasal disease with optic neuritis was common.

Dr. A. HILL GRIFFITH (Manchester) asked whether the cases described by Dr. Fish exhibited central scotomata in the field of vision and whether they were really cases of retro-ocular neuritis, for it was worth remembering that such cases commonly recovered even if untreated.

Dr. FISH, in reply, said that some of the cases were certainly retro-ocular neuritis, while others were as certainly papillitis.

PSYCHOLOGICAL MEDICINE.

THURSDAY, AUGUST 1ST.

Dr. F. PETERSON (New York) read a paper on

The Galvanometer as a Measurer of Emotions

in which he said that he had been much occupied during the past winter in the use of the galvanometer as an instrument of precision in psychophysical research. Féré, in 1888, was the first to discover the perturbations of the galvanic needle by emotional influences. Two years later Tarchanoff, a Russian, gave an account of similar experiments, which were corroborated by Sticker in 1897. In 1902 Sommer reported somewhat unfavourably upon the use of the galvanometer in this respect. E. K. Müller, an electrical engineer of Zürich, in 1904, experimenting on himself, led Veraguth and Jung to confirm Tarchanoff's work, and their results were published recently. His own experiments had been conducted with Dr. Jung at Zürich upon both normal individuals and cases of insanity and were published in *Brain*, July, 1907. They employed the mirror galvanometer of Deprez-d'Arsonval with a horizontal celluloid scale placed one metre from the galvanometer. A moveable indicator recorded the deviations of the light upon the kymograph. A rheostat was employed and usually one Bunsen cell. The electrodes used were copper plates upon which the hands or feet were placed. At times jars of warm water for contact were employed. As soon as the test person was placed in the circuit a rapid rise in the curve with some fluctuation took place, due to expectant attention, a form of emotion varying in different persons. This effect, however, soon subsided and the experiment proceeded. Various stimuli were employed—sensory, verbal, intellectual, and emotional—and were ordinarily repeated three times. In many cases word associations were used. Eight normal individuals and 11 cases of dementia præcox were experimented on. The galvanic wave began to rise in from two to five seconds after the stimulus in normal conditions, but in abnormal states the latent time was increased even from eight to 27 seconds. Every stimulus accompanied by an emotion deviated the galvanometer in proportion to the liveliness of the emotion aroused. Repetition brought about exhaustion of the power of the stimulus. A particular value was attached to the use of the galvanometer with word associations striking emotional complexes, which might prove useful in exploring the minds of neurasthenics, hysterics, the insane, and criminals. In cases of acute katatonia the galvanometer usually registered a straight line, showing an absence of emotion. Irregularities affecting the movements of the galvanometer due to respiratory or other physical influences were all readily differentiated from the purely psychic perturbations. Tarchanoff regarded the phenomena as due to a secretory current of electricity associated with the sweat glands. Sticker thought that the capillary system of blood-vessels was concerned in the manifestations, but the phenomena occurred when the Esmarch bandage was in use. Dr. Peterson was therefore inclined to believe that the sweat glandular system seemed to be the chief factor, producing a current under irritation or by altering conductivity. The pneumograph was simultaneously used with most of their experiments because of the proverbial influence of emotions upon respiration. Respiration being under conscious control when affected by emotions produced curves not only for the moment but for a considerable time afterwards, as shown by the pneumograph, whereas the galvanometer, being beyond the control of the will, showed waves quickly subsiding with the fall of the emotion.

Dr. W. F. MENZIES (Cheddleton) asked what interval of time elapsed between the application of the stimulus through the sweat glands and the movement of the galvanometer. He also stated that minute electrical currents resulted from muscular contractions in the cerebral circulation, which had to be taken into account.

Dr. F. W. MOTT (London) was of opinion that the phenomena were due to muscular action accompanying emotional states rather than to currents in the sweat system. He suggested that a plethysmographic record should be taken from the hands to compare with that from the galvanometer used with wet electrodes from the feet.

The PRESIDENT of the section (Dr. T. CLAYE SHAW of London) thanked Dr. Peterson for his able contribution which led him to hope that the emotions might be as accurately measured as were already the processes underlying sensation and memory. The use of the galvanometer might also possibly be investigated in criminal cases where there was often a sudden rise of emotion.

Dr. PETERSON briefly replied.

Dr. GEORGE M. ROBERTSON (Larbert) read a paper on

The Presence of a Bacillus in the Blood of Persons Suffering from General Paralysis of the Insane.

He said that the researches of which this paper was a summary were inspired by the Morison lectures by Dr. W. Ford Robertson and were undertaken with the object of confirming the definite conclusions to which he had come that "a diphtheroid he had named the bacillus paralyticans was the specific etiological factor in the production of general paralysis and tabes dorsalis." The observations were carried out under the direction of Dr. George Robertson by Dr. O. H. G. Gostwyck and Mr. J. Theodore Anderson, medical officers, and Dr. Winifred Muirhead, the bacteriologist, of the Stirling District Asylum. In conducting this research they avoided the mucous surfaces of the body.

severe pain. In perforation of the stomach or intestine the first pain is caused by contact of the contents with the parietal peritoneum. In gastric ulcer the paroxysmal pains are elicited by movements of the stomach dragging upon the parietal peritoneum which is hyperæsthetic on account of the lymphangitis due to the ulcer. Contraction or distension of a segment of bowel which is attended with traction upon its attachments to the abdominal wall is painful. The pain of intestinal obstruction appears to be due to stretching of the mesentery proximal to the obstruction. Wilms considers that a coil of bowel when contracting upon its contents at the proximal side of an obstruction tends to become straight in the same way as does the gut in sausage making. The mesentery prevents this and becomes stretched. Displacement of the peritoneum of the abdominal wall seems also to be a cause of pain. During laparotomies Professor Lennander passed into the abdomen his finger covered with a rubber glove and pressed on the anterior abdominal wall. The patient felt nothing, but as soon as the serous membrane was displaced against the muscles a feeling of pain was experienced which varied according to the degree of sensitiveness of the individual and the amount of displacement. The patients described their sensations as "like colic," "as if the bowel is being expanded by wind," "like bad griping pains." Professor Lennander therefore thinks that a displacement of the peritoneum takes place and produces pain as soon as a loop of intestine contracts on its contents, hardens, rises, and presses against the parietal peritoneum. These pains appear to occur not only in ileus but in cases of temporary irregularities of peristalsis in people not suffering from abdominal disease. The pains in hepatic disease may be explained as follows. The liver, gall-bladder, and the extrahepatic bile passages are without nerves of pain. But when the gall-bladder contracts to expel its contents the cystic and common bile-ducts and sensitive retro-peritoneal tissue are stretched.

THE BALKAN STATES EXHIBITION AT EARL'S COURT.

THE Balkan States Exhibition at Earl's Court is much more interesting and attractive than it may at first sight appear. The fact is that it is easier to organise an exhibition of one or two small States. What they have to show can be displayed within a reasonable compass, and these Danubian principalities have the further advantage of picturesqueness together with a recent and romantic history; they have only been independent nations for so short a time and had to fight so hard for their independence. Can it be possible that they have so soon taken rank among the civilised peoples of Europe? This question a visit to the exhibition will answer. Thus, in the Bulgarian Section there are admirable diagrams setting forth the development of the country. Gilded cubes give by their size an idea of the annual general trade, then of the trade with each nation, so that at a glance the progress of the country can be realised and it is seen which are the nations that have most contributed. The new laws of these new countries are in many respects in advance of the old laws of the old countries. Thus, and only considering that which affects public health, there is Article 7 of the Bulgarian Law on the work of women and children which says: "Night work in all industrial establishments is forbidden for boys under 15 years of age and for all women and girls irrespective of their age." Then there is a clause forbidding women to work for four weeks after child-birth. Other clauses insist that no work can continue for more than five hours without a rest, and the unwholesome hurry over meals is prevented by the law which stipulates that the interval from work shall last at least one hour. In the Servian Section the London visitor will not fail to be somewhat disconcerted when he sees photographs of the outdoor recovery schools of Belgrade. Here in London, only within the last few weeks, an experiment in this direction has been made at Woolwich. 100 children are having their lessons, their meals, and their recreation in the open air or under verandahs in the park belonging to the Woolwich Coöperative Society lent to the London County Council for that purpose. Place has thus been found for 100 children out of the seething populace of this huge metropolis; and here is the little capital of the little principality of Servia with its outdoor recovery schools in full working order, not as an experiment but as a well-established institution. There are also various exhibits of the Society for the Protection of the Health of the Servian Nation and of schools of cooking and domestic economy. The industries and natural products of Servia and those of Bulgaria are well and graphically exhibited, and on all sides evidence will be found of young peoples eager to advance. There is undoubtedly a great future for the Balkan peninsula with its mineral wealth, its agricultural produce, its beautiful scenery, and its vast ranges of mountains where the most invigorating and pure air gives life and force to a brave and strong race of people. In these countries also the cost of living is much less than in Western Europe and there are many mineral springs and beautiful places where health stations have been established, which only require to be better known to become very popular. Concerning all these matters fuller information can be obtained from the commissioner of the Servian Government.

SURRA IN THE FEDERATED MALAY STATES.

Dr. Henry Fraser, director of the Institute for Medical Research, Federated Malay States, and Mr. S. L. Symonds, the Government veterinary surgeon, have published in pamphlet form an "Interim Report on Surra" in that country. They say that trypanosomiasis in cattle and horses is on the increase and causes a great mortality among these animals in various tropical and subtropical countries. In horses the disease runs a rapidly fatal course and may quickly become epidemic; the clinical signs are those characteristic of surra; as a rule the microscopic demonstration of trypanosomes in the peripheral blood is easy. Cattle harbouring the parasites may for a long time appear to be in perfect health; apart from an occasional rise in temperature there are no clinical signs of the disease, and during this period microscopical examination will almost certainly fail to reveal trypanosomes. In the later stages the cattle become emaciated, the hair is scanty and dry, the poll is often denuded, and the animals are unable to perform much work. The most trustworthy method of detecting trypanosomiasis in cattle is by inoculation of their blood into rabbits and guinea-pigs, in the blood of which after a short period of incubation the parasites may readily be found. Biting flies of the genus tabanus are conveyors of the disease.

HOSPITALS AND SPECTACLES.

SOME time ago a number of philanthropic ladies initiated an Association for the Supply of Spectacles in London Elementary Schools. The spectacles which they proposed to supply were found to be of a very inferior quality, so that the authorities of the Royal London Ophthalmic Hospital (Moorfields) and other eye hospitals were unable to accede to the request of the association to fill in the cards issued by them. The price of spectacles supplied at Moorfields to patients of the hospital was at the time under consideration with a view to revision. Investigation showed that some reduction was possible whilst still leaving a reasonable profit for the manufacturers. The revised prices were therefore adopted, the price for simple spherical lenses being 1s. 9d., and that for sphero-cylinders of average strength 4s. 6d. We believe that

8·4 per cent. in cases of other forms of insanity. These figures were not meant to be taken as of true statistical value as the number of cases examined was not sufficient for that purpose, but they helped to confirm the findings of Eyre and Flashman who in a somewhat similar investigation found diphtheroid organisms present in 16·6 per cent. of cases of general paralysis, as compared with 17·6 per cent. of other forms of insanity. With respect to the examination of the blood and cerebro-spinal fluid of living subjects, he had examined the blood of 24 cases of general paralysis on 41 occasions by withdrawal of from five to 20 cubic centimetres of blood from the basilic vein. He had been unable to obtain a diphtheroid organism in culture from any of his cases, nor had he succeeded in obtaining such from the cerebro-spinal fluid withdrawn by lumbar puncture, which fluid he had investigated in nine cases of general paralysis and one of tabes dorsalis. He had, however, on a few occasions obtained growths in the forms of isolated colonies of different kinds of bacteria upon the agar plates which had been prepared from the centrifugalised deposit of broth culture of the blood, though the initial flask had remained sterile, and he thought that the liability to external contamination by this method was very considerable. Therefore, considering the ubiquitous nature of diphtheroid organisms, he was of the opinion that with such an elaborate method caution must be exercised before it was definitely stated that an organism so obtained did actually come from the circulating blood. With respect to the alleged improvement stated to have occurred in general paralytics as the result of treatment by the new vaccine, it might be mentioned that Dr. Lewis C. Bruce[1] claimed to have greatly benefited two cases of marked general paralysis by inoculating them with defibrinated blood taken from a case of general paralysis in the second stage of the disease. Again, temporary improvement of a greater or less degree was stated by Dr. Ford Robertson in May, 1903, to have occurred in certain cases treated with anti-diphtheritic serum, although in his later papers he claimed that his organisms were special and distinct species of the diphtheroid class. Moreover, it must be remembered that remissions were not infrequent during the course of general paralysis. It was possible, therefore, that the improvement which was stated to have followed the use of the new vaccine might be found to be only of a temporary character as in the previous instances, but time alone could decide. In view of the above considerations he felt justified in suggesting that whereas it was possible that diphtheroid bacilli, in conjunction with several other species of micro-organisms, might help to undermine the constitution of persons suffering with general paralysis, and thereby to hasten the progress of the disease, sufficient evidence had not yet been produced to warrant the statement that a particular species of this group was endowed with specific pathogenic and paralytic properties.

The PRESIDENT of the section thanked Dr. Robertson and Dr. Mott (on behalf of Dr. Candler) for their papers and invited discussion on them.

Dr. P. W. MACDONALD (Dorchester) inquired whether Dr. Candler had attended the recent meeting of the Medico-Psychological Association at which Dr. Ford Robertson and Dr. McRae had given the results of their latest researches.

Dr. C. MERCIER (London) considered that the presence of micro-organisms in general paralysis seemed more than a coincidence but that the subject must still be left in the hands of expert bacteriologists.

Dr. D. YELLOWLEES (Glasgow) was not surprised that varying opinions prevailed as to the rôle of bacilli in cases of general paralysis and he thought that important discoveries were close at hand.

Dr. ROBERTSON replied that at present he was only collecting facts.

DENTAL SURGERY.

WEDNESDAY, AUGUST 1ST.

Mr. J. MCKNO ACKLAND (Exeter), the PRESIDENT of the section, in opening the proceedings, referred to his advocacy of the establishment of the section of Dental Surgery as long ago as 1883. The previous record of the section was an excellent one and much had been done to elucidate the far-reaching consequences of oral sepsis. Too much stress could scarcely be laid on the supreme importance of not only efficient masticatory apparatus but oral hygiene in the present open-air treatment of pulmonary tuberculosis, and if proper and careful attention were directed to this point it was not unreasonable to presume that the increased efficiency of nutrition would still further increase the number of cured cases. The increasing amount of dental caries in persons of all social grades was a matter of national importance, and, to quote so eminent a physician as Professor William Osler, "more physical degeneration is caused by defective teeth than by alcohol." Mr. Ackland then alluded to the importance of the subject they were about to discuss and called upon Dr. G. F. STILL (London) to open a discussion on

The Causes, Effects, and Treatment of Dental Disease in Children

from the point of view of medicine, announcing that Mr. EDMUND OWEN (London) would open the subject from the surgical and Mr. J. G. TURNER (London) from the dental side.

Dr. STILL said that caries of the teeth was an important cause of ill-health in children and one which was liable to be overlooked; the converse was also true that ill-health in children was a cause of dental decay. Decayed teeth interfered with the proper assimilation of food, and such interference was most serious in childhood when growth and development, physical and mental, should be at their greatest activity. Any widespread prevalence of dental decay in childhood was a menace to their national physique. A series of observations taken amongst children brought to hospital for other conditions showed that 82·7 per cent. of children between five and 12 years of age had decayed teeth, and 39·8 per cent. of children between two and five years of age; some of these children had from ten to 15 carious teeth. Parents as well as medical men ought to know how much a child's health might suffer from decayed teeth. The commonest evil therefrom was digestive disorder; and this in a child was often shown by loss of flesh, loss of appetite, enlargement of the abdomen, and sometimes by frequent pains in the abdomen. Anæmia was also sometimes due to dental caries, perhaps in consequence of chronic poisoning from the foul condition of the teeth. Decayed teeth also formed a nidus for micro-organisms which might set up inflammatory disorders in the mouth or pass into the blood or into the neighbouring lymphatic glands and produce more serious disease. It had been thought that tuberculous disease of the glands in the neck might arise from infection from decayed teeth; the tubercle bacillus had been found in decayed teeth; and enlargement of glands was very frequently associated with decayed teeth, but it was very uncertain how often any tuberculous infection was due directly to the teeth for there were other—and probably much commoner—sources of infection; but there could be little doubt that indirectly the swelling of glands which certainly resulted from dental caries was a powerful predisposing cause of tuberculous infection of these glands. Decayed teeth were also a cause of frequent headaches in some children, and occasionally gave rise to more troublesome nervous disorder, such as habit spasm and in a few recorded cases even epilepsy. Lack of proper cleaning of the teeth was one factor but not the only one in the production of dental decay. Considerably more than 50 per cent. of children of the hospital class at the school age had never cleaned their teeth in their lives. But it had been shown that children of the well-to-do classes were just as liable to dental caries as the poor and less well-cared-for children; and whilst the most scrupulous cleanliness would not always prevent decay, complete ignorance of a toothbrush was not inconsistent with a perfect set of teeth. There were differences in the teeth of different children; in one the enamel was thicker and more perfectly formed than in another, and this difference might be congenital and perhaps peculiar to particular families, so that in the children of one family the teeth were more resistant to decay than in another; but imperfect development of the teeth, particularly of the enamel, might be due to a preventable disease—namely, rickets; and any profound disturbance of nutrition, such as was produced by improper feeding in infancy, might interfere with the perfect development of the teeth so that they were more liable to decay. Diet had some influence in producing decay in the teeth after they had already been cut; but probably this influence was chiefly indirect; any food which caused digestive disorder thereby altered the secretions of the mouth so as to favour the action of bacteria in producing acid fermentations and eroding the enamel. Sweets, which were generally supposed to injure of the pickers." It is amongst the so-called "foreign" pickers—i.e., those who are immigrants from large and sometimes distant towns—that the mission is active. It is obvious that the influence it is able to exert in raising the self-respect and standard of decent living amongst this class will result in an appreciation of the virtues of cleanliness that alone will be of value in safeguarding the public health of the hop districts, and we have an equal sympathy with the religious and social side of their work. Evidence of the care that the mission takes of the bodies of its charges is afforded by the fact that last season 20 trained nurses besides 40 missionaries and 33 lady workers were working for it amongst the 60,000 immigrant pickers in 37 parishes. Much of the work is voluntary and unpaid. The Rev. Francis G. Oliphant, honorary secretary to the mission, writes to us: "I will thankfully accept donations and subscriptions towards the £250 I have to raise annually, if sent to me at Teston Rectory, Maidstone, and parcels of illustrated literature for the reading-room and club tents, and bundles of old linen to aid the nurses in their ministrations to the sick, if forwarded to Wateringbury Station, S. E. and C. Ry." We gladly support this appeal, for we are assured that both the pickers themselves and the districts in which they are employed derive much benefit from the work of the mission.

---

A PLAN FOR THE REGULATION OF MOTOR TRAFFIC.

A LETTER from the chairman and secretary of the Motor Union of Great Britain and Ireland which has recently appeared in the daily press offers an admirable suggestion for the control of the motor traffic passing through small towns and villages on the main roads. There have been so many complaints from these quarters of inconsiderate and reckless driving on the part of some drivers of private cars that the Motor Union fears that farther irksome, and at the same time ineffectual, speed limits may be imposed. To prevent the exhibition of so unpleasant a remedy by the police authorities the Motor Union has resolved to attempt to cure the disease by the adoption of its own remedy. This has taken the form of the provision of road agents on the main roads, who will be provided with a badge and whose duty it will be to warn drivers of dangerous places, and to advise them when they are about to pass through villages where special care is required. The coöperation of the local police authorities has been obtained in many instances, and the agents appointed are in most cases retired members of the police force; it is intended to employ army pensioners in this manner also. The scheme will be a credit to the enterprise and resource of the Motor Union if it is fairly worked, and if the road agents coöperate with the police, and are not used as a means of avoiding police-traps. For the necessity of police-traps is unfortunately a real one. There are undoubtedly a proportion of motorists, both owners and chauffeurs, who will never regard the sign-post warnings or the dictates of common sense in driving. Some of these at present are kept in order by the police. We understand that the Motor Union will now undertake that if any of these bad citizens commit preventable damage after receiving due warning from a road agent (the altered significance of the term is pleasing) he will neither receive nor deserve any sympathy in his subsequent dealings with the local justices. There are two abuses that need control badly—one is the close cutting of corners and the other the anointing of the number plate with vaseline or other adhesive substance in order that it may collect dust and become illegible. The agents could be particularly useful in stopping this latter law-evading device. We do not expect that the scheme will meet with the hearty support of the public all at once; the public has suffered and is suffering much from motorists, and will like to see how the Motor Union scheme works before commending it.

THE Department of Public Health of Queensland, in a bulletin dated July 6th, states that up to noon on that day no case of plague has occurred in Brisbane since May 31st. As regards the Cape Colony, the medical officer of health states that for the week ending July 20th no case of plague occurred in King William's Town. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on August 9th states that during the week ended August 8th no case of plague was reported. As regards Hong-Kong, a telegram from the Governor received at the Colonial Office on August 12th states that for the week ended August 10th there were 4 cases of plague and 4 deaths from the disease.

SECOND INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

THE Second International Congress on School Hygiene terminated its work on August 10th and, as was probably to be expected, the view that the schoolmaster unsupported by medical training must be incapable of solving problems of school hygiene was generally adopted by all the meetings. This, in fact, is the message of the Congress, and if Sir James Crichton-Browne went further in declaring that its dominant note was that from henceforth schools must be more than ever under medical supervision and guidance we believe that he diagnosed the prevailing sentiment. It is a noteworthy fact that when the Education (Administrative Provisions) Bill was being considered by a Standing Committee of the House of Commons, a Member moved an amendment that only children should be inspected whose parents desired it, which was defeated by 32 to 1 after it had been pointed out that it was the duty of parents to subordinate their personal feelings upon matters concerning the health of the race.

Medical Examination of School Children in Gloucestershire.

Dr. MYER COPLANS (medical inspector of schools, Gloucestershire education committee) contributed a useful paper referring to the Gloucestershire experiment of 1904, which, he said, arose out of a desire on the part of the county education committee to improve the condition of certain elementary schools at which the attendance and consequently the grant-earning capacity had become seriously impaired by reason of the continued prevalence of contagious skin diseases among the scholars. It became his duty, however, to point out to the education authority that it possessed no statutory powers enabling him to carry out a scheme involving the medical examination of any child save with the parent's consent. Thereupon his committee gave him a free hand to devise and to carry out some scheme which, while satisfying the parents, would elicit especially the main facts relating to the degree of prevalence of contagious skin disease among the scholars. To that end he circularised the parents of some 8000 children and 97 per cent. gave their adhesion to the scheme which he then proposed. That scheme in effect was summed up by there being issued to each child a card which was intended to accompany the child throughout his or her school life. On one side of the card were particulars filled in by the parents concerning the child's ailments, the medical history, and questions as to tuberculosis in the family. On the other side were notes made by himself at regular intervals concerning the child's physical and mental development, condition of skin, state of vaccination, together with remarks when necessary on the special senses.[1] For each of the 60 schools under observation there was instituted a medical register on which was tabulated standard by standard the condition of individual scholars as shown by the card. He found the columns relating to the records of zymotic disease of great assistance in determining the probability of spread of any particular form of disease in any standard, department, school, or even village, and he recalled one case of a village concerning which the columns

---

[1] THE LANCET, March 11th, p. 653, and August 19th, 1905, p. 542.

After a few remarks from Dr. G. A. Sutherland (London),

Mr. K. W. Goadby (London) suggested that a common error of physicians was to ascribe caries of the teeth to digestive disturbances rather than to pathological conditions of the mouth. In considering the effect of dental diseases upon the gastro-intestinal tract it was important to distinguish between diseases of the soft parts of the mouth and diseases of the hard tissues or teeth. The former were the originators of the greatest amount of toxin production; the latter, destroying the functional character of the teeth, promoted disease in a more mechanical way. At the same time defective teeth frequently led to inflammation of the jaws and soft tissues. Mr. Turner had referred to the difference in fermentability of the mono- and polysaccharides; it was, however, important that the di-saccharide cane sugar was very resistant to fermentation by the majority of the bacteria inhabiting the mouth, as was also starch; maltose, on the other hand, being the chief sugar derived from starch by the action of ptyaline, was one of the most fermentable of all. Glucose or maltose invariably showed an acid reaction in neutral solution when inoculated with mouth bacteria within six hours, whereas cane sugar required 48 hours or more; this was of great moment in the production of dental caries in children as usually, except at night, the fragments of one meal were removed by the next before actual fermentation had progressed very far. Ulcerative stomatitis and pyorrhœa alveolaris showed a remarkable similarity in their bacteriology, histological character of the pus, and at times in their clinical aspects, and he was inclined to regard them as variants of the same disease.

Mr. Arthur W. W. Baker (Dublin) confirmed from his own experience the production of hypoplasia by whooping-cough and from influenza. Hypoplasic teeth were not more prone to caries than normal teeth; in fact, arrested caries was more common in these teeth than in normally developed ones.

Mr. R. Denison Pedley (London) made a few observations on the medical aspect of the question and discussed the various carbohydrate food-stuffs and their relation to dental caries.

Mr. W. R. Ackland (Bristol) submitted that the prevention of caries in young children rested much more with the parent, nurse, and medical man than the dental surgeon who only saw the child when caries was established. The medical man must educate the mother and the nurse. Children were frequently allowed the pernicious habit of eating biscuits or sweets in bed last thing at night. Want of cleanliness was, however, only one cause of decay.

Mr. C. Edward Wallis (London) said that he had made a number of observations on the relation of dental disease and epilepsy. Dental treatment of epileptic children was commenced two years ago and the method of drastic treatment had been adopted. In making careful examination into the statistics there was, however, no apparent diminution in the incidence or severity of the fits. In a large County Council school it had been unmistakeably shown that the children with the lowest physical and mental development were those who were classed as suffering from the largest amount of dental disease.

On the motion of the President of the section the discussion was adjourned until Thursday, August 2nd.

Thursday, August 2nd.

Mr. P. Sidney Spokes (London) stated that some years ago he had collected statistics of hypoplasic teeth which showed that the incidence was less common among the children who were better fed during the first three years of life than among the very poor who were afterwards found in parochial schools. With regard to treatment, among dental surgeons who took a wider view of disease than the saving of one or two teeth there was a strong feeling in favour of extraction whenever there was the possibility of danger to the health of the individual; at the same time it was only fair to point out that in many cases the temporary teeth might be made functional by "*stopping*," or by the application of nitrate of silver, in cases of superficial decay. The early discovery and prompt treatment of caries could only be secured by systematic periodical examination with dental probe and mirror.

Mr. J. F. Colyer (London) said he would confine himself entirely to the subject of treatment. The most important thing to remember was that children's mouths to be kept clean must be kept functional. First, then, mouth breathing tended to promote inflammation of the gums in the front of the mouth, with the sequelæ of caries, suppuration, &c. Promotion of nasal breathing was therefore to be insisted on. Secondly, with regard to treatment, filling might be performed when the pulp was not exposed but where this obtained extraction was the better course; in fact, the only cases where Mr. Colyer was inclined to adopt conservative treatment were in the second temporary molars of children under the age of six. The cases, however, which demanded most serious consideration were those in hospital practice where children were brought with the whole of the deciduous molars hopeless wrecks. If the first permanent molars were in place the best treatment was the removal of all the deciduous molars, and if one or two of the teeth be opposed by teeth not yet decayed the removal of these also was indicated, the loss of their antagonists in the corresponding position of the opposite jaw destroying their function and allowing them to either act as the initial points of further decay or as the starting place of oral sepsis. The question of oral sepsis in all its branches must be weighed in the balance against the loss of a few temporary teeth and in his (Mr. Colyer's) opinion the former far outweighed the latter.

The discussion was continued by Mr. F. Coleman (London), Mr. J. H. Gibbs (Edinburgh), Mr. F. J. Bennett (London), Mr. J. Lewin Payne (London), Mr. W. Russell Barrett (London), Dr. J. Milligan (Barrow-in-Furness), and Mr. G. A. Peake (Cheltenham).

The President of the section in summing up the discussion stated that he was most in agreement with the speakers who, although admitting the necessity of extraction of temporary teeth at times, were more inclined to adopt conservative measures when possible. With the suggestions urged as to improvement he was in hearty accord and trusted that the discussion would bear considerable fruit in the prevention of dental disease in children. In the absence of Dr. Still and Mr. Owen the President called upon Mr. Turner, who opened the discussion for the dental surgical side, to reply.

Mr. Turner, in replying to the discussion, said that two main questions appeared to have been raised in the discussion, the relation of diseases of the stomach to diseases of the teeth and the all-important question of treatment of temporary teeth. If the stomach did affect the teeth how was the influence brought about; was it by the eructation of acid from the stomach, for if so the amount of acid required would cause profound pathological changes in the œsophagus and pharynx. Was the influence, then, by an alteration in phagocytosis; if so, only the necks of the teeth were likely to be affected and caries in children more frequently attacked the crowns. Was it by alteration in the salivary secretions; perhaps, but neither dental surgeons nor physicians had any data for such a supposition, especially as the acid of lemonade acted as a mild deterrent to dental caries. The co-relation of anæmia and dental caries was apparently of the same order and it was more probable that the anæmia was the direct effect of the caries rather than the reverse. With regard to treatment, he adhered to the formula—any tooth which could not be rendered painless and aseptic should be removed, and Mr. Colyer suggested that functionless teeth should also be removed, as a functionless tooth at once became a dirty tooth; functionless teeth might be included in the above formula without any difficulty. Experience had taught him that the line of treatment was correct; there was no difficulty in feeding a child even if all but the four first permanent molars had been removed, while the child's health improved on the removal of septic troubles. Mr. Colyer's idea of isolating the first permanent molars by the extraction of teeth in mouths with much caries was good, as temporary teeth without proper opposition or occlusion became dirty teeth. The fact that rickety animals frequently possessed good teeth required more investigation.

Mr. Ackland read a paper on

Some Cases of Neuralgia.

The cases were divided into three groups for convenience of description: (*a*) those in which pain in one tooth was referred to another; (*b*) neuralgias and remote affections due to dental irritation; and (*c*) pain in teeth due to affections of other parts. The first class required only a brief summary. Pain was never referred across the median line but was often referred to the opposite jaw on the same side. The patient rarely localised the right tooth; when the pain was referred to the wrong tooth the cavity was usually interstitial.

would only bring about failure; a weak staff would make a complete inspection impossible; an inefficient staff would do far more harm than good, it would be far better to have no inspection at all. An efficient staff must be well paid with regard to the work to be done; a salary fixed on the scale of that now paid to district medical officers of health would not secure efficient inspectors.

Sir James Crichton-Browne (London) said that no teacher in these days could be regarded as thoroughly competent who was altogether ignorant of physiology or indifferent towards it, and so essential was a strict and scientific observance of its monitions, not only to sound and successful education but to national integrity, that the regular medical inspection of schools and school children, either as a state institution or under local organisation, had been established in France, Germany, Belgium, Austria, Norway, Switzerland, Russia, Servia, the United States, Japan, Egypt, the Argentine Republic, and Chili, and would, it was hoped, be adopted before long in this dilatory country.

The Health of the Teacher.

A special section devoted to the study of the needs of the teacher was presided over by Dr. T. J. Macnamara, M.P., whose thoughtful opening address is commented upon in a leading article.

The Play of School Children.

This subject was not neglected by the Congress and much interest was taken in a paper read by Mrs. Bland-Sutton on the work of the Children's Happy Evenings Association, which was the pioneer in the work of organised recreation. There were 136 branches in London and many affiliated branches in big towns in England. The association gathered together every week during the greater part of the year over 24,000 children, and in this work enlisted the services of over 1300 voluntary workers. Experience had convinced the association that this was a work in which the voluntary element must always reign supreme. Putting aside the cost to the ratepayer of an elaborate compulsory system of recreation estimated to cost £300,000 a year there was the objection that the work would become a mere matter of routine. In confirmation of this Mr. Pett Ridge said that the work of the Children's Happy Evenings Association was being carried on without costing the ratepayers a penny. During the last 18 years the association had taught the children of London that amusement was not necessarily confined to noisy quarrelling and they had encouraged cleanliness. He did not think that a combination of paid and voluntary workers would prove satisfactory in a large scheme. After Dr. Gulick, President of the Child Playground Association of New York, had said that the games of England were the final word to the rest of the world, Mr. Cope Cornford spoke in favour of the Children's Happy Evenings Association. He pointed out that the defect of the official system proposed was that it would take away the responsibility of parents in regard to the play of their children.

Should Children Attend School before the School Age?

In the seventh section there was a crowded attendance on Wednesday morning to hear Dr. Arthur Newsholme's (Brighton) paper on the Limit of Age for School Attendance. Professor W. Osler was in the chair and many members showed great eagerness to speak; indeed, very warm feeling was manifested. Dr. Newsholme's object was to denounce the growing habit of sending children to the elementary schools before the school age, urging that no child should be admitted who was not five years old. In 1904–05 elementary education in England and Wales cost £18,398,616, or 72*s.* 10*d.* per scholar, and he estimated that of this sum £1,749,711 were spent on children who were only three to five years old. They overcrowded the schools, contracted and spread infectious diseases, and did not lead natural lives. The speaker quoted the result of tests made of the atmosphere in such schools and in the poor homes from where the little children came, showing that the school was worse than the home. There were, however, exceptional children, notably those whose mothers went out to work, for whom it was a benefit to be at school before the age of five years, but these scarcely amounted to more than 10 per cent. of the total attending school before the age of five years and for such cases crèches should be provided.

Dr. A. H. Hogarth (London) read a paper in the contrary sense. The age from three to five years was as important as any other period. The remedy to existing grievances was not the exclusion of children of that age but the improvement of the infant schools or class rooms. They must select teachers possessing special aptitudes for dealing with these very young children; the surrounding sanitation had to be improved and the curriculum better adapted to their age. Two objections to the presence of such young children might be made on medical grounds. First, that it produced an increase in measles. On the other hand, the school was a means of teaching the parents the importance of this malady and at school a better watch was kept for the after-effects which were the most dangerous aspect of this disease. If there were more cases of measles there was no evidence to show that there was an increase of mortality from measles resulting from early attendance at school. The cases cited to demonstrate that the air in schools was more unwholesome than in the homes were old and only proved the obvious fact that there was room for better sanitation. It had been said that before five years the children derived no educational advantages, but what did this mean? Dr. Hogarth did not think that such children should be taught to write and read but to play in such a manner as to help the development of their muscles. Our methods were faulty because they were repressive and kept children hours without laughter. The children must be taught to laugh, to shout, to scrub, to put things in order, and all kinds of manual efforts that interest and create exercise.

Mr. Willis Bund thought that no general rule would apply. There were such wide differences, notably between town and country schools. In one case it was the school, in another it was the home which was the most unhealthy. To propose to send these children to crèches was no solution because there were grants to schools and not to crèches; but crèche methods could be employed in schools. As for disease, a good service was rendered in getting early history of cases.

Mr. R. C. Elmslie (London) agreed with this latter point. Tuberculosis of the bones and joints was often noticed between the ages of four and six years and if treated thus early serious deformities could be prevented. The same might be said of rickets, some forms of paralysis, and so on. They had more to do than to educate: they had to detect and to prevent.

Dr. H. Franklin Parsons (London) pointed out that in many schools younger children accompanied their elder brothers; they were not entered on the school books but they occupied the school floor and helped to vitiate the air. He was in favour of keeping the children under the school age, not out of ideal schools, but out of the schools such as they exist. They were far better off in a fairly well-regulated home. They should be careful not to lower the fundamental instinct animating all warm-blooded animals, that of keeping the offspring by the mother during the earlier years of life. Nor was it generally the case that mothers sent these very young children to school because they had to work; as often as not it was merely because the absence of the children gave the mothers more time to gossip over the garden wall.

Mrs. Kirk rose to speak from the teacher's point of view. At first she thought children should remain at home till the age of five years, but she would be puzzled how to manage a school were it not for these very young children. She was able to train them and their example when they grew up kept the class of older children in order. It was not the poor that behaved so badly but all classes. Then these very little children from very poor homes were made to keep themselves clean and to take exercise, and the mothers were invited to the school in the evening and received much educational advice. The mothers' instinct was good but they were dreadfully ignorant. Then these little children were not kept in badly ventilated class-rooms but in play-yards and in the open air. They had many toys, were taught to build and to play, and as for measles the speaker found cases were much more frequent after than before the holidays.

Mr. Mundella said that for 50 years the schools had been open to these young children and he doubted if it would be legal to exclude them now. The expense had been exaggerated. The crèche or infant school should be under the same roof or close by the general school and under the same authority.

Dr. H. Meredith Richards explained that at Croydon they did not exclude children, but would not allow overcrowding. At a school in the slums the children under five years who attended belonged to the better class. What was needed was to exclude the children who went to school and compel the attendance of those who did not go.

Dr. R. H. Crowley (Bradford) was strongly for the principle that children should be at home. There was a danger that translucent clot formed in the fluid on standing, which in purulent states was adherent to the containing vessel and more easily broke up. Normally the fluid deposited but few cells, two or three in the field of an oil immersion lens. These were much increased in disease. The polymorphonuclear cells predominated in cerebro-spinal fever, while in most acute local states the lymphocytes were more numerous. With congestion and œdema of the meninges the tension of the fluid was raised, so that it jetted out of the needle. These features were of value in discriminating between the true and pseudo-meningeal states in a young child. Both in children and adults syphilis was associated with lymphocytosis. In cases of suppurating otitis media with cerebral symptoms an examination of the fluid might decide between a localised abscess and diffuse suppuration of the meninges or between a toxæmia and meningeal suppuration such as occurred in cerebro-spinal fever. As regards bacteriology, the detection of the several organisms not only assisted diagnosis but afforded opportunity for preparing suitable vaccines. Lymphocytosis occurred usually before micro-organisms were to be detected. In regard to treatment, the value of lumbar puncture was mainly in forwarding remedial measures by aiding exact diagnosis. Decompression by evacuating fluid might be of value in some cases, but he did not approve of it in cerebral tumour. So far, in hydrocephalus relief had only been afforded in a few cases and for a brief period, and in acute meningitis the beneficial effect was not permanent in tuberculous cases; some instances of posterior basic disease ran a favourable course after lumbar puncture Some advantage might accrue from the removal of toxic fluid, which might account for improvement in cases of uræmia with coma, convulsions, and Cheyne-Stokes breathing, as such fluid exhibited an increased toxicity towards the lower animals.

Dr. F. E. Batten (London) based his observations on 42 cases in which lumbar puncture had been performed on children between one and two years of age. In one instance no fluid could be obtained in four attempts, and in all but three, in whom the sitting position was adopted, the operation had been performed with the patient lying on the side. He divided the cases into 12 groups. 1. Of 12 cases of tuberculous meningitis the fluid was clear in 11 and opalescent in one. In all tension was raised, the amount of albumin was increased, and the number of leucocytes were considerable, lymphocytes representing 91 per cent. of the whole. Tubercle bacilli had been found in the clot. 2. In six cases of cerebro spinal meningitis the fluid was turbid and the cells were increased, polymorphonuclear cells representing 93 per cent. The diplococcus was found in all. Four recovered completely and one died subsequently from diphtheria, the evidence of thickening of the meninges being found post mortem. 3. Three cases of pneumococcic infection. 4. One case of streptococcic infection. 5. Six cases of convulsions, with two immediate recoveries. 6. Intracranial tumour (three cases); in one the quantity of fluid had increased to 18 ounces at the fourth tapping. 7. Hydrocephalus. The fluid was clear and was of specific gravity 1010, with increased albumin. 8. Cerebral diplegia. 9. Anterior polio-myelitis. The fluid was clear and sterile. 10. Congenital syphilis showed definite increase of lymphocytes. 11. Acute ataxia (two cases). The fluid was normal. 12. Spinal caries. Clear rhombic crystals were present. Dr. Batten considered lumbar puncture of value in confirming the diagnosis in tuberculous and cerebro-spinal meningitis, both by the distinctive cocci and differential cell count. Therapeutically it relieved intracranial pressure was easy of performance, and free from ill-effects.

Professor W. D. Halliburton (London) said that the source of the cerebro-spinal fluid was the epithelium of the choroidal plexuses, together with exuded lymph, since it contained waste products of nervous activity. The chief variations were in pressure and the chemical and cytological characters. The chief chemical features were the presence of a small amount of protein which was increased in pathological states, a small and variable amount of sugar, and cholein derived from lecithin in the disintegration of nervous matter and present only in organic lesions.

Dr. F. C. Eve (Hull) suggested that the flow of cerebro-spinal fluid was dependent on vascular tension and could be promoted by slight pressure on the veins of the neck.

Dr. J. Porter Parkinson (London) said that lumbar puncture would assist the diagnosis between pneumonia and meningeal or cerebral disease with marked cerebral sym

Dr. E. Athole Ross (London) described his experience in the technique and diagnostic features of the various cells found. He recommended Leishman's stain.

Dr. Purves Stewart (London), after criticising the ordinary methods of cell counting, said that an accurate estimate could be arrived at by taking the cerebro-spinal fluid, adding a fixed proportion of a staining-agent to it, and counting the cellular elements in a special counting chamber, just as was done in the case of blood corpuscles. Owing to the scantiness of the cells in normal cerebro-spinal fluid a larger counting chamber was required than in the case of blood. Fuchs and Rosenthal had devised an excellent modification of the Thoma-Zeiss chamber for the purpose which Dr. Stewart had been using for several months. In health the number of cells per cubic millimetre varied from one to four or five, such cells being lymphocytes, with an occasional endothelial plate, never any polymorphs. In a series of eight successive cases of tabes the average number of lymphocytes was 72·3; in four cases of general paralysis of the insane the average was 190·4. In seven cases of cerebro-spinal syphilis the average was 37·6, and so on. The figures thus obtained corresponded to what had been found before with the old centrifuge method, but they were more trustworthy. They demonstrated the well-known fact that, as a rule, the lymphocytosis of tabes and of general paralysis was far greater than that of ordinary syphilitic affections of the central nervous system. This rule of lymphocytosis in tabes was not without exceptions. Dr. Stewart cited a case of well-marked tabes with most of the classic signs, in which the cerebro-spinal fluid on one examination contained only 3·3 lymphocytes per cubic millimetre and a week later a second observation in the same case only showed 11 per cubic millimetre. Dr. D. Ferrier recently had a similar case and Dr. Stewart understood that Babinski had had one also. So far Dr. Stewart had not come across a case of general paralysis without well-marked lymphocytosis. With regard to the significance of polymorphonuclear leucocytes in the cerebro-spinal fluid, their presence was always pathological and indicated an acute process within the meninges. The most marked cases were those of acute suppurative meningitis. Dr. Stewart had counted as many as 28,933 polymorphs per cubic millimetre in a suppurative meningitis, while counts of 200, 300, and 400 were exceedingly common in pneumococcus or diplococcus meningitis. But the presence of polymorphs did not necessarily mean a suppurative infection: it simply meant an acute process. As an acute septic meningitis subsided the polymorphs gradually became replaced by lymphocytes and ultimately even the lymphocytes disappeared as the cure was completed. Lastly, it was interesting to note that a marked polymorph leucocytosis might occur without any organismal infection whatever, as Dr. Stewart had noted within a few hours after injecting sterile salt solution into the cerebro-spinal fluid of monkeys.

Dr. A. Gardner Robb (Belfast) spoke of 300 cases of epidemic cerebro-spinal meningitis in which lumbar puncture was performed during unconsciousness due either to coma or induced by chloroform; he used rather a large trocar and cannula as he often had to deal with thick pus. In many cases which were "hanging fire" the operation appeared to start convalescence.

Dr. W. Essex Wynter (London) remarked that the 16 years through which Dr. Barrard had traced lumbar puncture would not include a case in which the speaker had, so far as he knew, originated the operation in 1889 and which with four others was published in The Lancet in 1890 under the title "Puncture of the Theca Vertebralis for the Relief of Pressure." Examination, post mortem, showed that in nearly every case described as tuberculous meningitis the real condition was general tuberculosis and this discouraged attempts to relieve the local condition by this means. Then followed the employment of lumbar puncture for diagnostic purposes and later the injection of cocaine or other local anæsthetic for relief of pain. In the spring of the present year a case of sporadic cerebro-spinal meningitis with coma was treated by removal of spinal fluid containing the meningococcus and the injection of a saturated watery solution of acetozone on several occasions with complete recovery.

Dr. Reginald L. Langdon-Down (London), in opening a discussion on

Precocious Development,

confined his attention to the psychical side and drew the following conclusions. The precocious children were those from whom they drew their great men, that was, those who inadequate. He presented a formidable array of statistics on the actual prevalence of ringworm in the West of London schools. He argued that as the law forced children to attend these schools the State should see that they were properly treated for the diseases they contracted while at school. As a first step in this direction every child at school should be thoroughly and periodically examined by a competent medical man.

On this question Dr. **MEREDITH RICHARDS** read a paper in which he explained that at Croydon cases of ringworm when excluded from school might either be treated privately or else gratuitously by the local authority. At the municipal dispensary sometimes drugs and sometimes x rays were employed. In the latter case the average duration of the treatment did not extend over eight weeks, whereas with drugs the time required was much longer. As there might be a relapse all cases should be carefully watched for three weeks after recovery.

Dr. **HARRY G. CRITCHLEY** (of the educational medical staff, likewise of Croydon) contributed a paper showing that a tenth of the absences from the London schools were caused by ringworm and Croydon lost £300 a year in education grants in consequence of ringworm. The microsporon Audouini he did not think was amenable to treatment, but the larger spore, the trichophyton megalosporon, could be rapidly and safely cured by the use of x rays. This had caused a great reduction in the number of pupils at one of the two ringworm schools of the Metropolitan Asylums Board which was formerly always full.

Dr. **V. HÜTTEL**, school physician of the *City of Prague*, communicated a paper summarising

The Various Perils Besetting School Children,

not omitting spinal curvature and nerve diseases due to overwork. All this clearly showed that to each school a physician must be appointed as the guardian of the pupils' health. This medical adviser must have not only the duty to advise but the power to see that his advice was followed. Dr. Hüttel may be said to have summarised the upshot of all the discussions held in Section VII. Thorough medical inspection of all school children, this preferably under the national health authority—namely, the Minister of Public Health or the nearest approach to such a Ministry as exists—was evidently the chief remedy for existing evils which the section was able to suggest.

The last day of the Congress was devoted to pleasure excursions and many members travelled to Cambridge, others to Haslemere, to Hindhead, and to Brighton. A popular excursion was the visit arranged to Windsor Castle and Eton College and the trip organised to Oxford found many adherents.

THE INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS: COMMITTEE MEETING AT LONDON.

(FROM OUR SPECIAL COMMISSIONER.)

(Concluded from p. 404.)

AT the conclusion of the morning sitting of the first day the committee was entertained at lunch at his house by Mr. J. Bland-Sutton who entertained his guests in his marvellous reproduction of the Persian hall built by Artaxerxes Mnemon. Here they were met by other members of the British Association of the Medical Press, notably the President, Mr. Thomas Wakley, and Dr. H. P. Cholmeley of THE LANCET, Mr. H. W. Armit of the *British Medical Journal*, and Mr. L. E. Creasy of the *Clinical Journal*, and honorary secretary of the association. Being a fluent speaker in French, which is the official language of the association, Mr. Adolphe Smith was appointed to speak on behalf of the British branch, and in the circumstances felt bound to give some explanation concerning the hall in which they were assembled. He pointed out that the inscription on the wall showed that the original hall, which Mr. Bland-Sutton's archæological knowledge has enabled him to reconstruct, was placed under the protection of Ormuzd, Anahita, and Mithra—that is to say, the good forces in nature, the feminine forces in nature, and the solar god or male fertilising force, and he explained the symbolic meaning of the designs and decoration with which everything was in harmony, from the esoteric meaning of the jewels which Mrs. Bland-Sutton was wearing to the flowers that decorated the table and the character of the menu.

Professor **POSNER** of Berlin and Dr. **BLONDEL** supported the toast proposed in honour of Mr. and Mrs. Bland-Sutton. The builder of the palace, so beautifully reproduced, was called Artaxerxes Mnemon, said Professor Posner, and Mnemon was an additional name given to him on account of his retentive memory, but it would need no exceptional gift of memory for all the guests to recall the present scene.

Dr. **DOLÉRIS**, who spoke subsequently, also insisted on the charm of the reception and was especially grateful for being admitted into the intimacy of a British home.

In responding, Mr. **BLAND SUTTON** expressed his gratification to find that not only the artistic beauty but the symbolic meaning of the Persian hall which he had reconstructed were so fully understood and appreciated.

When the banquet had terminated the members of the committee went upstairs to the drawing-room and there resumed their labours. The grievances and the difficulties described in the reports made at the morning sitting were now discussed with the object of finding a remedy.

Dr. **DOLÉRIS** lamented the fact that the medical press could not hope to obtain any help from French manufacturers; they would not betray medical men who had offered to render them services, yet the situation was absolutely intolerable. The articles that were written for manufacturers and paid for by them were so skilfully worded that they deceived medical men themselves. Such deception was most injurious to the public and to the profession, but how was it to be prevented?

Dr. **DÉJACE** (Belgium) said that the prophylactic action taken by the German *Association of the Medical Press* showed the use of such societies as theirs. Here was an inspiring spectacle of the honest manufacturer and the honest journal seeking to help each other. In Belgium they would certainly endeavour to profit by the work and example of the Germans. But then, of course, it must be recognised that in Germany the customs and the laws were very different. For instance, in Germany the police bought drugs, analysed them, and not only published the result but stated what it cost to make the drug. This was done to prevent the public being deceived either as to the nature of the article or of the price at which it ought to be sold.

Professor **POSNER** pointed out that a journalist in his own country would probably be able to distinguish between a legitimate criticism or notice and a "puff"; but abroad this could not be done so readily. For instance, a German journalist reading a French article written about some French product would be more easily deceived. Therefore the English and the French should not harbour what had been rejected in Germany. The Germans, on their side, would pay full attention to warnings sent them by the other nations that formed part of the International Association of the Medical Press. It often happened in Germany that a manufacturer would advertise in a medical journal and at the same time would send an article praising the articles advertised. As a rule, the journal would refuse to publish such as article, but this might not prevent the manufacturer from advertising. Later the manufacturer would send another article in which the most guarded mention is made of his products, and as the article would be thoroughly scientific and in reality very ably written it might get published, but the writer was paid by the manufacturer. This ought not to be allowed.

Dr. **BLONDEL** explained how this sort of thing was sometimes managed in France. A medical man might be engaged in research and was doing good work. He might be approached by a manufacturer who would ask him for his genuine opinion. To give such an opinion experiments were necessary, guinea-pigs and various things would be needed, and, of course, it was only fair that the manufacturer should reimburse such out-of-pocket expenses. This he did not fail to do and on the most lavish scale. As the drug or whatever it might be is in those cases really good, an excellent report was likely to result from such experiments. This was not an easy situation to deal with as it is so very difficult to draw the line between what was legitimate or otherwise. Then there was the great question of the entire article and the synopsis of the article. The article was often an obvious puff but a summary of the article sent round to the press might lead people to think that it was nothing of the sort. He thought that the remarks showed some current curves obtained by this instrument which were very beautiful and instructive, those illustrating the "current of action" given off by the heart being particularly interesting.

The PRESIDENT then showed

Some Tracings of Medical Coil Currents.

This was an amplification of his paper read in the Section of Medicine at Oxford in 1904. He showed how the presence of an iron core increased the length of the waves even to the extent of their interfering with each other. He said that short waves were much more pleasant and bearable than long waves, and he showed how by the placing in the circuit of a very narrow spark gap an otherwise undesirable current became almost ideal for testing purposes.

Dr. HUGH WALSHAM (London) and Dr. J. F. HALLS DALLY (London) jointly communicated a paper on

The Orthodiagraph,

in which it was stated that in this instrument the centre of the x ray tube or diaphragm, the centre of a small screen, and a marking pencil were all in exact line and all moved together freely in any desired direction. As the centre of the screen was passed over the chest of the patient a series of dots was made on the marking screen by the pencil, and as only those rays which came in a straight line from the centre of the anode were made use of an accurate outline of the heart, &c., was obtained comparatively easily and was quite free from distortion. Judging by the diagrams shown it would seem that the heart shadow as ordinarily seen in screen examination of the chest was about double the size of the heart itself.

The first morning's proceedings concluded with a paper by Dr. W. F. SOMERVILLE (Glasgow) on

The Effects of High-Frequency Currents on the Urinary System.

His general observation was that the amount of urine was increased, but in some cases where polyuria was present it was diminished. A large number of chemical analyses were given which tended to show that a course of high-frequency treatment tended to improve the metabolism and general nutrition of the body.

THURSDAY, AUGUST 1ST.

The second day's proceedings were opened by Dr. J. MACKENZIE DAVIDSON (London) who started a discussion on

X Rays and Sensitive Plates.

Dr. Davidson had carried out a large number of experiments of a most exhaustive nature, working out the influence of tubes of various degrees of vacuum upon the several brands of plates on the market. The whole trend of his researches went to prove the superiority of the French plates, the next best coming a long way behind.

A large number of those present took part in the discussion, all of whom were, in the main, of the same opinion as Dr. Davidson.

Mr. ELLIS PEARSON (Bideford) then read a paper on

The Use of the X Rays from the Point of View of the General Practitioner,

in which he insisted on the necessity of being up-to-date, and after giving a *résumé* of the general value of the rays in diagnosis and treatment showed how it was the duty of every medical man to make proper use thereof in the interests of his patient.

Mr. E. W. H. SHENTON (London) then followed with an address on

The Examination of the Hip-joint.

Mr. Shenton insisted on the importance of using the tube below the patient and carefully screening the case before taking the radiograph. Several lantern slides were shown and stress was laid upon the arch formed by the top of the obturator foramen and the neck of the femur. He said that so long as this arch line was not disturbed there could not be any great injury present. In case of fracture or dislocation the disturbance was very great.

Dr. DAVIDSON insisted on the value of the stereoscopic method in hip examinations and considered it to be superior to any other.

Mr. SHENTON replied.

Mr. J. R. RIDDELL (Glasgow) read a paper on

The Measurement of the Brim of the Female Pelvis by Means of X Rays.

This method consisted, he said, in laying the patient prone on the couch with the tube below and on a line drawn at right angles to the centre of the plane of the brim of the pelvis. The plate was placed on the buttocks so as to rest as nearly as possible on the back of the sacrum and tuberosities of the ischia. The shadow of the brim thus obtained was carefully measured, and, allowing for the position of the tube, brim, and plate, the actual size of the brim was arrived at by a comparatively simple calculation. The method would appear to be sufficiently accurate for all practical purposes. From experiments on the cadaver the error was found to be so very small as to be almost negligible.

Dr. J. GOODWIN TOMKINSON (Glasgow) read a paper on

A Method of Treating Lupus Vulgaris,

in which he said that the treatment consisted essentially of mild scraping, exposure to x rays, and the use of Unna's creasote plaster in turn, with intervals of rest. He had found it of great value and showed lantern slides of cases where it had been employed with considerable success. The method was recommended where the Finsen method was unavailable or too expensive.

Mr. JAMES TAYLOR (Bristol) read the notes of a case of Paget's Disease Treated by X Rays.

The second day's proceedings were brought to a close by Dr. A. HOWARD PIRIE (London), who read a paper entitled

"The Measurement of the Reverse Current in an X Ray Tube and a New Meter for Estimating the Dose of X Rays,"

in which it was pointed out that the method was based on the electro-decomposition of water and the instrument was placed in series with the x ray tube. If it was desired to measure the inverse current the gas given off by the two electrodes was collected separately and the proportion of direct and inverse currents arrived at by calculation. For estimating the dose of x rays the gases were not separately collected. The instrument employed was described and illustrated in THE LANCET of July 13th, 1907.

FRIDAY, AUGUST 2ND.

The third day's proceedings were opened by Dr. J. H. SEQUEIRA (London) with a paper on

X Ray Dosage.

The paper was based upon the experience gained during the past two years in the skin clinique at the London Hospital. In that period 16,000 exposures had been made to the x rays by measured doses. Although large doses had been given there had been no dermatitis. The older method of frequent exposures and the risks of cumulative effects were contrasted with the present method of giving larger doses at stated intervals under the control of instruments of precision. Dr. Sequeira laid stress upon the importance of realising that there was a definite latent period between the administration and the reaction and cited Kienbock's classification of the degrees of reaction. In the first stage there was a period of latency of three weeks. The reaction was without inflammation but the hair fell out and lupus nodules became smaller. A larger dose caused the second degree of reaction which appeared after a latent period of 14 days. In the third degree the latent period was of ten days' duration, the reaction was more severe, and was accompanied by vesication, superficial erosion, and exudation. A telangiectatic scar resulted. In the fourth degree the reaction might appear in a week and was of the necrotic type with severe ulceration. In order that the various degrees of reaction might be obtained it was necessary thoroughly to know the apparatus which was being used and to measure the current in the primary circuit by the voltmeter and ampèremeter, to regulate the frequency of the interruptions, and to maintain the resistance of the tube. The alternative spark gap and the milliampèremeter in the secondary circuit were guides to the resistance of the tube. The penetration was estimated by a Benoist's apparatus and the output of rays was estimated by the pastilles of Sabouraud and Noire. The B tint, which was equivalent to five Holtzknecht's units, was taken as the guide. This dose was sufficient to epilate without producing an erythema. It was the dose used in the treatment of ringworm of the scalp and sycosis. In the case of rodent ulcer a large single dose was administered and then a fortnight was allowed to elapse before the same area was treated again. The dose varied. For an ulcerated surface a pastille dose would suffice; for an indurated edge the dose might have to be double this. These large doses might be were made into a subsection and united with the dentists. At Paris they were again put with the otologists. All the laryngological societies had passed resolutions against such treatment and this time they were allowed to separate at the eleventh hour and form two sections. As a result their meetings proved a great success. But when they appealed that the same course should be pursued at Madrid the Spanish took absolutely no notice of their communications, so nobody went to the congress. At Lisbon they were told they must work with the dentists, and therefore they again abstained from attending. Thus, since the Paris congress of 1900 they had not met at all. They did not want to separate from the medical congress but they had been forced to do so, and there was to be a special congress of laryngology at Vienna next year. As they also proposed to attend the general Congress of Medicine at Budapest, after failing to meet for eight years, they would have two congresses in two years. If they were treated thus by their medical colleagues how could they ask governments for any sort of favour, such as the creation of a chair of laryngology? Then many blunders were made by local committees in nominating honorary presidents. The experience acquired at one congress must be utilised at the next congress; there must be continuity.

Dr. BLONDEL agreed and related that the dentists had encountered similar difficulties and there were terrible disputes as to whether a dentist could be a dentist unless he was also a medical practitioner. He did not think one nation was competent to select presidents of honour from among the distinguished men of another nation.

Professor POSNER said he had been asked to nominate three foreign presidents.

Dr. DEJACE said that in Belgium the Government made such nominations and they would appoint a medical man not because he had any special experience in the question at issue but because he was a Senator.

Dr. DOLÉRIS remarked that there was no section of laryngology at Madrid because there were no distinguished laryngologists in Spain. The same reason applied to Lisbon but it did not apply to Paris, Berlin, or Vienna.

Mr. ADOLPHE SMITH urged that the management of a congress should be intrusted to those who had experience of congresses and were good organisers and not to a person merely because he held a high position or was distinguished in some branch of science. Such eminent men were likely to be too busy to attend to the drudgery and routine details of a congress.

Dr. DAWSON WILLIAMS pointed out that for the much easier and simple purpose of the annual meetings of the British Medical Association they had found it necessary to institute a Court of Appeal. The proposals coming from the locality where the meeting would be held were generally accepted. Still, it was sometimes necessary to correct them. Finally, the committee adopted the following motion:—

> The International Association of the Medical Press considers that it is necessary to establish a continuity between the international congresses and expresses the desire that a permanent bureau be created. This bureau should consist of the presidents and general secretaries of the national committees of the former congresses and the bureau of the forthcoming congress, together with the general secretaries of the former congresses of medicine and the general secretary and the president of the International Association of the Medical Press.

The committee now took the Budapest Congress into consideration. Mr. ADOLPHE SMITH related that when the Congress of Hygiene met there nothing whatsoever was done for the press. Fortunately he found an energetic French colleague and together they prepared a general strike of the press and this brought the congress to its senses and the necessary facilities were finally obtained. So it might be well to take time by the forelock. Speaking also from personal experience Dr. BLONDEL confirmed this opinion and proceeded to enumerate all that was needed. The various items mentioned were approved, as also that the general assembly of the press association should meet at Budapest in 1909.

After a few words about the right of reprinting articles Dr. DAWSON WILLIAMS moved the following proposition, which was adopted unanimously:—

> The committee of the International Association of the Medical Press, taking into consideration the question of the rights of authors, is of opinion that the author of an article published in a medical journal has not the right to authorise commercial firms to reproduce his article without having previously obtained the sanction of the editor or publisher.

A few more observations were made as to the regulation of *controversies* in journals and this concluded the business.

The committee now rose and proceeded to Oddenino's Imperial Restaurant in Regent-street, where they were entertained to a farewell luncheon by Mr. Thomas Wakley, President of the British Association of the Medical Press. After luncheon Professor POSNER proposed the health of Mr. Wakley. He had often, he said, longed to see England, *but somewhat* dreaded the journey. However, having taken that step, he was now gratified with the rare sight of an English blue sky. *Abroad*, if they had not been taught to admire the English climate they had long ago learnt to admire the authority and influence which THE LANCET had acquired. He begged Mr. Wakley to believe they were all very grateful to the President of the British section and would be pleased to explain in other lands the high position to which the British medical press had attained. Their association was as yet in its infancy, but those who had helped in its rearing would in the future have good reason to be proud of their work. Dr. BLONDEL spoke in grateful terms of his long relations with THE LANCET and its Editor and the toast was drunk heartily. Mr. WAKLEY replied, expressing his gratification at being able to help forward so good a cause and his pleasure at welcoming the representatives of the press of different nations.

Dr. DAWSON WILLIAMS now proposed the "Health of the President of the International Association of the Medical Press, Professor Posner." He praised the business-like manner in which Professor Posner had conducted the business and thought more solid work had been done at this London meeting than on any previous occasion. They had dealt with very difficult ethical questions and yet had passed resolutions which were likely to meet with the approval of the medical profession in all countries. The toast was seconded by Sir FELIX SEMON. In responding Professor POSNER proposed "The General Secretary," Dr. Blondel, who had been the soul of the society. Dr. DÉJACE, for Belgium, and Dr. DOLERIS, for France, proposed the health of the Honorary Secretary of the British Association of the Medical Press, Mr. L. Eliot Creasy, who had organised in so complete and pleasant a manner all the details of the reception of the committee in London.

This concluded the series of toasts and the congratulations which were the natural outcome of the two days' useful work carefully done and successfully accomplished. The members of the committee now parted company, some to return to their own country, others to attend the International Congress on School Hygiene.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7229 births and 3637 deaths were registered during the week ending August 10th. The annual rate of mortality, which had been 12·4, 11·9, and 11·7 per 1000 in the three preceding weeks, was 11·8 in the week under notice. During the first six weeks of the current quarter the death-rate in these towns has averaged 12·1 per 1000, the rate in London during the same period being 11·9 per 1000. The lowest death-rates in the 76 towns last week were 3·8 in Willesden, 5·0 in Walthamstow, 5·2 in Hornsey, and 5·5 in King's Norton; the highest rates were 17·4 in Blackburn, 17·7 in Sunderland, 17·8 in in Rochdale, 18·6 in St. Helens, and 21·7 in Stockton-on-Tees. The 3637 deaths in the 76 towns last week included 378 which were referred to the principal epidemic diseases, against 397, 396, and 362 in the three preceding weeks; of these, 104 resulted from diarrhœa, 94 from measles, 85 from whooping-cough, 40 from scarlet fever, 40 from diphtheria, and 15 from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered last week in Bristol, Brighton, *Plymouth*, South Shields, or in 12 other of the 76 towns; the annual rate from these diseases, however, ranged upwards to 2·7 in Walsall, in Blackburn, and in Merthyr Tydfil, 2·9 in Wigan, 3·9 in Stockton-on-Tees and in Cardiff, and 5·1 in St. Helens. The fatal cases of diarrhœa, which had risen from 39 to 78 in the four preceding weeks, further increased to 104 last week, and caused death-rates ranging upwards to 1·3

Pharmacopœia. The exhibit included Johannis lithia and potash waters. A very fine exhibit of mineral waters was that of the Chemists' Aerated Mineral Waters Association, Limited (Camwal), of Camwal Works, Bristol. One excellent non-alcoholic drink prepared by this firm is a very palatable pale dry ginger ale which contains a minimum of sugar. The exhibit included also a novelty in the shape of a "splitlet," a bottle smaller than the "split" size and containing a small quantity of soda-water representing the quantity usually consumed with spirits. Messrs. Ingram and Royle, Limited, of East Paul's Wharf, 26, Upper Thames-street, London, E.C., exhibited a large selection of natural mineral waters. There were also specimens of Carlsbad and Vichy salts. The Friedrichshall Company, of 10 and 12, Milton-street, London, E.C., exhibited the well-known natural aperient mineral water of Friedrichshall. It contains the sulphates of magnesium and sodium in nearly equal quantities, the usual dose being from one to two tumblerfuls. It also contains the chlorides of magnesium and sodium which are said to modify advantageously the action of the sulphates. Lastly should be mentioned the excellent samples of Devonshire cyder exhibited by Messrs. H. Whiteway and Co., of the Orchards, Whimple, Devon. Samples were submitted for tasting purposes and the verdict was obviously a favourable one.

VI.—PUBLICATIONS.

Amongst the publishers exhibiting books on modern medicine and surgery were W. B. Saunders Company, of 9, Henrietta-street, Covent Garden, London, W.C.; Mr. Sidney Appleton, of 25, Bedford-street, Covent Garden, London, W.C.; Mr. H. K. Lewis, of 136, Gower-street, London, W.C.; and Messrs. Rebman, Limited, of 129, Shaftesbury-avenue, London, W.C.

On previous occasions we have included in our notice of the annual exhibition a miscellaneous section, but this year there were no exhibits coming under this head.

ERRATUM.—In the report which appeared in our issue of August 10th of the Section of State Medicine at the British Medical Association held on Thursday, August 1st, Dr. J. H. Drysdale of London was erroneously reported as speaking in the discussion on the home contamination of milk. The speaker was really Dr. C. R. Drysdale of London.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 15th, 1829.

DR. AMUSSAT'S METHOD OF ARRESTING HÆMORRHAGE.*

To the Editor of THE LANCET.

SIR,—M. Amussat, doctor of medicine, and lecturer on anatomy in Paris, having lately been employed in very interesting experiments, on the "*tortion of blood vessels," as a means of stopping hæmorrhage*, has requested me, through Mr. John King Dingle, his pupil, who witnessed those experiments, to insert, in your extensively read Journal, a short account of his discovery. It appears that this gentleman was led to devise his new means of stopping hæmorrhage, by reflecting on the well-known canon in surgery, that "torn wounds do not bleed." His first essays were made on dogs and horses; having divided arteries in these animals, he bruised and lacerated the vessels in a variety of ways, but always without producing a durable suspension of the bleeding. After many attempts, he found that twisting the artery a sufficient number of turns was an effectual styptic, and, in his opinion, a more simple and expeditious, and less painful method than the ligature. Dr. Amussat's experiments were made in the presence of some of the most distinguished surgeons in Paris, and repeated before the Royal Academy of Surgery, and the general opinion entertained is, that his mode of operation will be one of the greatest utility, especially in the army and navy, as it enables the surgeon himself to secure the largest artery without the aid of an assistant.

The following is his mode of proceeding: Each orifice of the bleeding vessel, whether artery or vein, is to be seized with a pair of small forceps, so constructed as to be kept close with a spring; the vessel is then to be drawn out and separated from the different tissues which surround it, and a certain portion is to be insulated with another forceps, probe-pointed, and to be held in the left hand, for the purpose of limiting the effect of the tortion, which would otherwise affect too great a length of the vascular tube. The tortion is to be made with the right hand on the elastic forceps; ten half turns of the forceps will suffice to repress the flow of blood, and twenty will tear through the tissue of the vessel. It is necessary, after every three or four turns, to relax the hold a little, to allow the retraction of the artery or vein.

The rupture of the middle and inner tunics takes place, most frequently, after ten half turns, and these are forced back into the area of the artery, so as to form a valve, which is closely involved by the cellular coat; it is recommended, however, to twist the end of the artery off, as it presents a greater degree of security, and has been attended with more satisfactory results. The doctor's plan is supported by numerous proofs derived from instances of complete success. To render the tortion more easy, it is necessary to draw the artery well out from its connexions, and the twisting ought to be confined either with the thumb and index of the left hand, or with the blunt-pointed forceps before mentioned.

M. Amussat, after having successively and comparatively tried all the different means hitherto adopted in the suppression of hæmorrhagy from arteries and veins,—having used every kind of ligature that has ever been recommended, —having plunged the extremities of arteries into the most powerful and concentrated acids,—and after pressing, crushing, bruising, turning up, and pushing back the bleeding extremities,—has found no process so certain, or so often successful, as that of tortion. The twist, if properly executed, is not only sufficient to withstand the *vis à tergo* of the column of blood, but will bear, without detriment, the friction of a sponge in cleaning the surrounding parts. After having assured himself of these facts on the lower animals, M. Amussat tried whether this process were applicable to the human body. He put in practice his tortive experiments on the tubes of every calibre, from the narrow channel of a ramus cuniculus to the main canal of the aorta. To ascertain the quantity of resistance which the torsion would offer to the column of blood, he injected, with a powerful syringe, into the twisted arteries of a dead body, a fluid of equal density with the blood, but in no instance did the bulwark of the twisted extremity give way, although, in several instances, the coats of the arteries were ruptured by the force of the pressure employed. M. Amussat has not communicated to me any examples of its application on the living subject.

To illustrate more cogently the principles which this justly-celebrated physiologist wishes to establish, I shall suppose a case of divided radial artery. Each of the bleeding extremities is to be laid hold of by the self-shutting forceps already described; the flow of blood being thus arrested, the operator seizes hold of the forceps, already fixed on the artery, and gently extends the vessel from its sheath, whilst, with the probe-pointed forceps in the left hand, he grasps the artery about three or four lines from its extremity, and presses the sides together, thus limiting the extent of the tortion, which is next to be affected. The insulated piece of artery is now to be twisted to ten or twenty half turns, and the conical end of the vessel remains perfectly secure. By the traction first applied, the elastic external coat is drawn over the two inner and less versatile tunics, the ends of which are rolled back, so as to plug up the mouth of the tube, and afford a safe basis for a coagulum. The consequent effusion of lymph guarantees the success of the process.

Of the practicability of M. Amussat's plan I have had no personal experience, and I therefore do not presume to offer an opinion. I am, Sir,

Your obedient servant,

D. O. EDWARDS.

Westminster Hospital,
6th August, 1829.

P.S. M. Amussat has also invented an improved lithotritic apparatus, and an instrument for dilating the urethra.

---

* This letter was not received until after the account of Dr. Amussat's method of arresting hæmorrhage, given at page 520, had been sent to the press.—ED. L.

(Vide "Looking Back" in THE LANCET of August 10th, 1907, p. 407.)

VOLUNTEER CORPS.

Royal Garrison Artillery (*Volunteers*): 1st Cinque Ports: Surgeon-Lieutenant E. A. White, resigns his commission (dated, July 4th, 1907).

VITAL STATISTICS OF THE FRENCH NAVY.

The last vital statistics issued in respect of the French Navy are interesting. Average strength (officers and men) at home, 36,669; abroad, 9393; total, 46,062. Sick-rate, at home, 1012; abroad, 1396 per 1000 of strength. These rates, which include slight cases (*malades à la chambre*), are much lower than the corresponding rates in the land army. In both forces the chief causes of inefficiency are acute bronchitis, sore throat, influenza, gastric derangements, and rheumatism, but lesions due to accident are proportionally more frequent among the sailors. Death-rate, at home, 6·44; abroad, 5·11 per 1000 of strength. At first sight it would seem as if the mortality on foreign service were lower than on home service, but in reality this is not so. Invalids from abroad are sent to depôts in France, thus greatly augmenting the deaths reported from the latter. In 1903 the depôt death-rate was over 14 per 1000. Since 1899, when statistics were first published by the French naval authorities, the annual death-rate has been as follows: 1899, 6·61; 1900, 11·04; 1901, 6·80; 1902, 7·30; and 1903, 6·17. The year under consideration consequently compares favourably with the four that preceded it. The invaliding-rate for 1903 was 28 per 1000 of strength, but out of a total of 1307 men who were placed in retirement on account of ill-health no fewer than 604 were rejected immediately on joining, chiefly on account of eye affections, hernia, and tuberculosis. The remainder of the invalids, who had all served at home or abroad for longer or shorter periods, suffered for the most part from tuberculosis. For the foregoing information we are indebted to an article by Dr. J. Alvernhe in the *Archives de Médecine et de Pharmacie Militaires* for June.

SPECIAL PAY FOR MEDICAL OFFICERS IN INDIA.

The Government of India has announced its intention of granting special pay to officers of the Royal Army Medical Corps and of the Indian Medical Service. The allowance will be payable to officers below the rank of Lieutenant-Colonel for special sanitary, surgical, or medical work done for the State which it is not in the power of an ordinary medical officer to perform with the same efficiency as the specialist. It will not be a personal allowance but will be granted only to incumbents of certain specified appointments. There will be 105 specialist appointments in India, each carrying pay at the rate of Rs.60 a month. Of these, 55 will be allotted to the Royal Army Medical Corps and 50 to the Indian Medical Service in military employment. The special subjects are as follows: (*a*) prevention of disease (including parasitology, bacteriology, and preventive inoculation), 40 appointments; (*b*) dermatology (including the prophylaxis, treatment of, and instructional measures in connexion with venereal diseases), 10 appointments; (*c*) advanced operative surgery, 20 appointments; (*d*) ophthalmology, 10 appointments; (*e*) electrical science (including skiagraphy), 10 appointments; (*f*) mental science, 2 appointments; (*g*) otology, laryngology, and rhinology, 3 appointments; and (*h*) midwifery and diseases of women and children, 10 appointments.

Correspondence.

"Audi alteram partem."

SOME REMARKS ON PLAGUE.

To the Editors of THE LANCET.

SIRS,—To those interested in plague work let me commend the Croonian Lectures delivered by Professor W. J. R Simpson and just concluded in THE LANCET of July 27th. Professor Simpson's remarks will be subject-matter for much thought to those in whose hands lies the hygienic administration of India. The whole problem of scientific work in India, so far as the medical aspect of it is concerned, is an excellent example of what Professor Ronald Ross calls "unscientific administration."

In a letter published in *Nature*, June 13th last, Professor Ross shows up the many obstacles to good work that meet one at every turn in India, and all those who have worked in that country will bear witness to his remarks. But although the handling of the medical profession leaves much to be desired, *vide* Professor Ross's letter, the problem, so far as plague is concerned, is one not lightly to be got over. It is very easy to say, do this or do that, and in this country, where the welfare of each individual is the concern of the multitude, we cannot understand why any scheme for the general good should meet with opposition. Are we not apt to forget that it has taken centuries to arrive at this happy condition?

Anyone who has the smallest knowledge of Indian life knows the innumerable obstacles that rise up to baffle your efforts in every direction. Eliminate Bombay, Calcutta, Madras, and at most three or four other large cities in India, and what do we find? Millions of people, uneducated, bound down by caste rules, living on superstition, ready to believe the word of anyone so long as it contains the slightest trace of the supernatural. People whose customs of to-day have come down to them since India was. People who see in every passing cloud the finger of some irate god. Go back to the cities that have been eliminated. You will find three-fourths of the native population still hugging the superstitions of their forefathers, still anxious to be left alone with their troubles. And what of the educated fourth? In the majority of these educated minds there still lurks the shadow of superstition, and the man with the university degree will, when his child yawns, crack his finger-joints so as to frighten away any evil spirit that may be hovering round ready to find a lodging in his child's inside. In the face of all this the task seems hopeless.

There is another element, and this of a more serious nature, that has to be contended against. Many of these educated persons use their higher intellectual powers not for the general good but for their own individual advancement. They do not scruple to make use of the superstition and ignorance that surround them on all sides. Here is one case of many that came under my notice. In 1900 the proprietor and editor of a certain paper in Sind came forward as usual for inoculation, he and all his family, as soon as plague made its appearance. That done, he commenced a tirade against inoculation in his paper; not satisfied with that he accused the local plague authorities of brutality in the exercise of their duties. He went further and accused a native doctor of some offence connected with plague work. Government prosecuted. He was found guilty, sentenced to a term of imprisonment and a fine. He appealed and went on appealing until in 1902, just before the Delhi Durbar, he was acquitted. The native doctor, who had received some Rs.200 as compensation for the wrong accusations, was called upon to refund this amount. That man used to do no end of harm by his articles. He and his kind are some of the drawbacks to advancement in many parts of India.

But notwithstanding all these and many other unmentioned obstacles there can be no doubt that the plague question in India leaves much to be desired. The administration during the first few years was faulty, and now or for the past few years the jump has been too far in the opposite direction. To begin with, the material in hand was not properly utilised. Railway inspection was everything. No doubt it prevented the spread of plague to a certain degree, but it was impossible to make supervision complete; moreover, the men might have been more usefully employed. What I suggested in 1900 I am still inclined to hold to. That is, that if a certain number of medical gentlemen had been engaged, then placed either singly or in pairs throughout India in centres where plague was bad and just commencing, given an entirely free hand and allowed to make their investigations unmolested something of importance would more than likely have been discovered. It is only by living in a district where plague makes its appearance, runs its course for a certain number of months, then completely dies down, that one by constant watching, by daily investigation of each and every element that is likely to come into play, may discover the means by which plague is carried over the quiescent period. Such work cannot be done in a large city, there would be too many avenues to watch, but it can be done in an area including a certain number of small villages. Then at the end of six months, 12 months, or longer if necessary, let all the investigators be brought together and a conference held.

In July, 1906, the *Indian Medical Gazette* published a Special Plague Number. The subject was "How does Plague Spread?" It is generally admitted that the following may be speculative, which of late years have been put forward as likely to afford solutions of the "housing question," and we have no desire to minimise the difficulties by which that question is surrounded. They are so great, and of such a nature, that the whole subject appears to us to be one of national or imperial concern, which should no longer be left to private or even to local enterprise, and which urgently *requires the intervention of the legislature. It is clearly* necessary that every centre of population should be rendered able to provide shelter for its industrial elements, who, if left to find house accommodation for themselves, are certain to become the prey of a very undesirable set of speculators, and equally certain to provide centres of physical and moral evil from the effects of which their better housed neighbours cannot hope to remain exempt. It is very urgent that avoidable evils arising in the homes of the lowest classes of the community, and especially among those who live by unskilled labour, should be sternly repressed by law; if necessary, by the methods employed in some continental countries, such as compulsory labour colonies and separation of the sexes, so that the great educational power of the magistrate may be brought to bear upon the classes most in need of enlightenment. In addition to these influences we want that of the school, such as it might be made if managers and teachers would learn that their business is to educate, not merely to impart the rudiments of the three R's, and to educate chiefly in those directions in which the home influences surrounding the pupils are misleading or defective. Such directions, in the homes which most require amendment, are not difficult of discovery. The children who come from them have need to learn the first principles of conduct. Assuming Mr. BURNS to be correct in his view as to the necessity of higher wages, the children have to learn that the way to get higher wages is to deserve them. They have to learn that a dirty and overcrowded home means disease and death as well as the extent to which these evils can be kept at bay by an observance of the first rudiments of sanitation. By some agency or another, it cannot be doubted that decent houses will in the future be provided for all who are fit to be trusted with them; and the development of this fitness will be the proper work of the school, as soon as those responsible for conducting it can emancipate themselves from traditions which have long lost all vitality and are mere survivals of more primitive times. If the principles of conduct were taught to both sexes, and the arts of cooking and housework to the girls, it would in time become possible to leave the submerged, the slattern, the incapable, and the sot, to be dealt with according to their deserts by properly constituted authorities.

"Rheumatoid Arthritis."

AN interesting discussion took place at the recent meeting of the British Medical Association which was held at Exeter on Rheumatoid Arthritis and the Morbid Conditions which Simulate it, with Special Reference to Pathology and Treatment (see p. 440 of our present issue). *The classification* and diagnosis of diseases of the joints which bear a resemblance to rheumatism and gout are acknowledged to be matters of considerable difficulty. The practitioner is liable to become confused as to the various terms employed to designate morbid changes in the joints, which changes may be ill-defined or so similar as to be scarcely distinguishable one from another. The speakers who took part in the discussion on rheumatoid arthritis well illustrate the divergent views which are still held as to the condition popularly known as "rheumatic gout." Whilst some practitioners deprecate this term as inexact, inasmuch as they maintain that the disease has no connexion with rheumatism or gout, others still hold that some relationship exists between the maladies. The question is naturally of considerable importance, since the treatment must depend upon the causal factors that produce the changes found in the joints and upon the extent to which we are prepared to regard the condition as a distinct clinical entity.

The very lucid statements of Dr. ARTHUR P LUFF, who opened the discussion, probably express the views held by the majority of physicians, although the remarks uttered by subsequent speakers indicate the arguments which may be urged against those views. With regard to terminology Dr. LUFF used the words "rheumatoid arthritis" throughout, although he admitted that the term was open to the objection that it presupposed a causal relation between the condition and rheumatism. "Arthritis deformans" would perhaps be more correct, and "osteo-arthritis" might be employed, but Dr. LUFF preferred to restrict this term to the "so-called forms of monarticular rheumatoid arthritis which were always traumatic in origin," a limitation which is surely not generally observed. Dr. LUFF rightly pointed out that rheumatoid arthritis is a constitutional disease, not a local one, the affection of the joints being only a part of the morbid process. This is of importance in respect to treatment, especially when mechanical methods are employed. It is now generally accepted that rheumatoid arthritis is a disease due to micro-organisms gaining access to the blood, probably through the alimentary tract, although invasion may also take place from the nose, pharynx, or air tubes. It is also acknowledged that various predisposing causes exist, such as excessive work and strain, debilitating conditions (especially influenza), a neurotic disposition, and traumatism.

From a practical point of view the diagnosis and treatment of the disease are of supreme interest. Early diagnosis is of first importance, since it is evident that better results will be likely to follow if the nature of the malady is recognised and suitable treatment is employed before deformity of the joints manifests itself. The early stages of the disease are characterised by rapidity of pulse, local sweatings and progressive involvement of joints. The tachycardia is persistent, scarcely any variation being observed by day or night. Many observers have also drawn attention to the spotty pigmentation so frequently seen in the skin of patients suffering from this disease. Cold extremities are also a characteristic feature. Whilst these general symptoms may suggest the nature of the illness attention is naturally especially directed to the condition of the joints. In the acute form, as Dr. LUFF pointed out, the synovial membranes are primarily mainly affected, while the ligaments are softened and infiltrated, presenting the well-known spindle-shaped enlargement of the joints. The cartilages are damaged secondarily, and it is not were also met with amongst other and less civilised communities. During the early part of this year I wrote to medical men practising in various parts of the world, asking them if they would kindly inform me as to the frequency with which hernia was met with amongst the native races in their respective districts. The information very kindly furnished me is of considerable interest, and it would appear that hernia has not only a wide geographical distribution but that the more common varieties as seen in this country prevail all over the world. It is somewhat remarkable that femoral hernia is so seldom met with in certain districts. The influence of employment as regards the incidence of hernia is also clearly brought out. The following are some of the letters I have received:—

Dr. G. Duncan Whyte *of Swatow, China.*

Hernia is of frequent occurrence in this neighbourhood, mostly inguinal, and usually on the right side. For example, a hospital here bought five and a half dozen trusses for right inguinal hernia, and only one a half dozen for the left side. Out of, roughly speaking, 15,000 patients I have seen in China I have only once diagnosed a femoral hernia. I have not heard of anyone here or in Swatow who stocked trusses for femoral hernia. Last year I saw a curious case in which there was a very small hernia in the linea alba, midway between the xiphi-sternum and the umbilicus. There had been neither injury nor disease locally and the same condition had existed in the patient's father and (paternal) grandfather. About eighteen dozen trusses are sold in Swatow in the course of a year, a town with a population of 20,000 by night and 30,000 by day. The extra 10,000 come in from all the villages around to earn their living by coolie work, &c. Tight prepuces are common and the straining to express urine may be expected to accentuate any congenital defect that exists. The Chinaman would not dream of having his foreskin cut any more than most of them will consent to have extra digits removed; they wish to preserve their whole body complete. They all "hunker" to defæcate, an attitude which by supporting the walls of the inguinal canal, or by securing that a man shall only defæcate when his hernia is reduced, may diminish the chances of strangulation, but to my mind this attitude does not have that influence upon the incidence of hernia which I was led in my student days to anticipate. On the other hand, its causal relation to hæmorrhoids and more markedly to prolapse of the rectum seems to me beyond question.

Dr. A. Sims *of Matadi, Congo State.*

Hernia is most common here. I should think 3 to 5 per cent. of the adult male population is affected with it. Formerly, when there was no railway and all goods were carried to the interior on men's heads, hernia was more common than now and strangulated hernia was very common. Native products are now only carried, at least in these parts, for short distances, and in consequence hernia is diminishing. Child labour for carrying burdens is growing less and as a result I see fewer children with hernia.

Mr. Malcolm A. Smith *of Bangkok.*

I should consider hernia to occur as frequently here as it does in England. I have, however, in five years' practice never seen or heard of a case of strangulation of the bowel.

Mr. B. Granvill Corney *of Fiji.*

From personal observation I can say that inguinal hernia is of common occurrence amongst the members of the Fijian race. Umbilical hernia is also very frequently met with in Fijian children, though it usually becomes less apparent as they grow up. I have seen one case of obturator hernia in a boy of 12 or 14 years of age.

Mr. A. J. Glanville Barker *of Sarawak, Borneo.*

Hernia is fairly common amongst all the races we see here—viz. Malays, Dyaks, Chinese, and Indians.

Dr. Edward H. Armitage *of Honolulu.*

The following statistics have been furnished to me by the surgeon to the Queen's Hospital in Honolulu. From June 1st, 1904, to May 13th, 1907. Total number of cases operated upon, 54. Nationality: Hawaiian, 7; part Hawaiian, 2; other nationalities, 45. Varieties—inguinal: single, 40; double, 8—total, 48; femoral: single, 5; double, 1—total, 6. Sex—Male: inguinal, 46; femoral, 4—total, 50. Female: inguinal, 2; femoral, 2—total, 4. Strangulated, 3; non-strangulated, 51.

I am, Sirs, yours faithfully,
R. W. Murray, F.R.C.S. Eng.,
Surgeon, David Lewis Northern Hospital, Liverpool.
July 17th, 1907.

THE DISCUSSION ON ACUTE NEPHRITIS IN CHILDREN AT THE BRITISH MEDICAL ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—May I point out that your report of my remarks on acute nephritis in children on p. 390 of THE LANCET of August 10th is misleading. The gist of my statement was that ocular manifestations were conspicuous for their absence in *acute* nephritis. Amaurosis without ophthalmoscopic signs occurs as in adults. The typical picture of albuminuric retinitis—neuro-retinitis with a star-shaped figure at the macula—which occurs rarely in cases of intracranial pressure without renal disease in adults, is relatively common in these cases in children.

I am, Sirs, yours faithfully,
August 9th, 1907. J. Herbert Parsons.

⁂ We have much pleasure in inserting Mr. Parsons's correction. Our reports have to be somewhat condensed and hence there is always a liability to ambiguity.—Ed. L.

EXPERIMENTS ON PROLONGED PROTEIN FEEDING.

To the Editors of THE LANCET.

SIRS,—In a criticism of my paper on protein feeding Dr. Chalmers Watson expressed the opinion that more than one of the thyroid glands therein illustrated are pathological and not as I stated normal, but to my request for enlightenment as to what points he relied on in forming this opinion he has replied that he prefers to postpone giving any reasons. Seeing that the criticism is one which, if substantiated, would materially affect one of the conclusions of my paper I hope Dr. Watson will appreciate the desirability of supporting his statement by some facts, however brief.

I am, Sirs, yours faithfully,
Harley-street, W., August 10th, 1907. David Forsyth.

INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

To the Editors of THE LANCET.

SIRS,—I attended all the general meetings of this important Congress and I spent many hours in Sections II., VII., and X. during the past week, but with the exception of a passing reference by Mr. L. M. Bowen-Jones of Carmarthen on Friday the Sunday schools were not mentioned (to my knowledge) either in any set paper or by casual debaters. The entire omission of Sunday schools from the programme of a congress on school hygiene is a curious fact and difficult to account for. As far as my own experience goes Sunday schools are frequently the foci and hotbed of infectious diseases and any closure of day schools will be useless unless accompanied by that of the Sunday schools in the same district. It is true that the scholars are only in the Sunday schools for from one hour to one and a half hours once or twice in the day, but the buildings are often much overcrowded, badly lighted, insufficiently ventilated, and otherwise ill adapted for their purpose.

I consider that the powers of the local sanitary authority for dealing with Sunday schools are not so stringent and easy of application as they ought to be, for some types of Sunday school managers are not gifted with common sense and they can only be influenced and made to do right by the exercise of legal powers strictly applied.

I am, Sirs, yours faithfully,
Sidney C. Lawrence,
Medical Officer of Health and Delegate from Edmonton.
Edmonton, August 12th, 1907.

AN ASSOCIATION OF SHIP SURGEONS.

To the Editors of THE LANCET.

SIRS,—Would you allow me through the medium of your valuable columns to issue an appeal to all ship surgeons, both past and present, urging them to join the B.S.S.A. (British Ship Surgeons' Association), which is being formed with a view to improving the "status" of medical officers to shipping companies and also to obtain more "clinical" and "experimental" evidence on the treatment of "sea-sickness" and other "affections" peculiar to sea-going persons. It is proposed ultimately to issue a *Ship Surgeons' Gazette* monthly, that is, if the membership permits. We have every reason to believe that it will have the substantial support of all shipping companies, seeing that it will indirectly further their interests. Further particulars can be obtained from, and application for membership to be sent to,

Yours faithfully,
G. Metcalfe-Sharpe,
Surgical Officer.
Angram Hospital, Middlesmoor, Leeds, August 8th, 1907.

one aspect of the matter which is liable to be lost sight of by inquirers in this field. The teachers as well as the taught deserve consideration. They are equally exposed to risk of ill-health if the condition of the school be insanitary. Light and air, recreation and rest, are as needful for them as for their charges. Their very efficiency as teaching machines depends on the preservation of their faculties in the best working order. We are glad to find that at the Congress a special section was devoted to a study of the teachers' needs and that it was opened with a thoughtful address from DR. T. J. MACNAMARA, M.P., who when he descends from the partisan platform to a consideration of matters in which he is an expert, is always a weighty and an interesting speaker. Two main points were emphasised in his remarks. The first was the importance to the teacher of conditions favourable for making himself heard by his audience. The profession of teaching involves an almost continual use of the voice and the resulting strain thrown on the larynx is very great. Many members of our own profession have opportunities for realising the degree of effort involved in delivering even an hour's lecture when the speaker has to contend against the noise of street traffic or any similar disturbance. But the duties of a school teacher are considerably more arduous, inasmuch as his labours are continued for many hours each day and involve not merely the fairly congenial work of delivering a prepared lecture, but the more wearisome effort of expounding elementary and therefore uninspiring matters to immature minds, with much wearisome repetition and amplification. In addition there is the necessity of maintaining discipline among a class often much too large for convenient handling, since financial pressure tends to keep down the number of teachers employed to the lowest limits. If, then, owing to the position of the school or to some other defective condition, additional difficulties are placed in the teacher's way the task becomes more than normal health and strength can overcome. Fortunately, most schools are placed at a distance from busy thoroughfares, if only in consequence of the annoyance caused to neighbouring residents by the young barbarians at play and by the vociferous enthusiasm of their exits. But now and again schools are unsuitably placed as regards traffic, and the teacher has to do his work amid the rattle of carts and the rumble of heavy vehicles, struggling pitifully to make his voice audible through the tumult which surges through every open window and door. This unequal struggle of the voice against the outside hubbub must be maintained throughout school hours. It cannot be wondered at that many a breakdown of health is caused by such conditions. Even in favourable circumstances the trial of the vocal powers of the teacher may be considerable and it would be well to arrange for instruction to be given to them in right methods of voice-production which may prove a striking boon to an uninstructed speaker. Nor must the general mental strain of teaching be forgotten and the need for sufficient time for rest after the day's work. Medical men have only too often to insist that delicate children shall not be made to spend their out-of-school hours upon home lessons; the same rule should apply to the teacher, who needs a fair interval of rest to prepare for the labours of the morrow.

A second important point dwelt upon by DR. MACNAMARA was the incidence of pulmonary tuberculosis on school teachers. Experience of any hospital for chest diseases certainly bears out the extent of the evil in question which is unfortunately easier to indicate than to remedy. The disease is apparently one of indoor life and the teacher's time must be mainly spent within doors. The actual opportunities of infection within the school building are not, we should think, serious, since children with tuberculosis seldom expectorate and such behaviour in school would at once be checked. Still, the ventilation of school buildings is not a very easy matter to arrange; it is difficult to avoid some closeness of atmosphere during lessons, especially in winter. Any lurking tuberculous infection is thus liable to be stimulated. A remedy must be sought first in diffusion of the knowledge of the danger incurred by violation of the laws of health and of the value of fresh air in combating the malady. Here to be forewarned is to be forearmed, and those who realise the danger of a vitiated atmosphere will be less likely to be seduced by the attractions of shut windows or terrified by that domestic bogey, a draught. In the summer classes might be held out of doors with benefit to both teacher and taught when other circumstances allow, but in urban schools this cannot often happen. Time out of school may be spent in the open air, and open windows at night must be the rule. The cultivation of some outdoor pursuit, such as golf or cycling, will be a great aid to a healthy life on the part of the teacher. We are brought back again to the principle upon which we have so often insisted. Since lack of knowledge is still the first cause of those imprudences by which health is endangered, due instruction of school teachers in the elements of hygiene must be insisted upon, not only that they may teach the laws of health to the children but also that they may practise them themselves; and when these laws are matters of universal knowledge more will have been accomplished for the happiness of the nation at large than by the most attractive scheme of social plunder that has ever beguiled the enthusiastic reformer.

Annotations.

"Ne quid nimis."

THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THE Fourteenth International Congress of Hygiene and Demography will be held in Berlin from Sept. 23rd to 29th. On Sunday, Sept. 22nd at 8 P.M. there will be a reception of members at the Neues Königliches Operntheater (Kroll). On Sept. 23rd the inaugural meeting will be held in the same place at 11 A.M., after which the exhibition will be opened in the Reichstag buildings, where also the meetings of the various sections will take place. The afternoon of that day will be spent in visits to local institutions. The sections will meet at 9 A.M. on Sept. 24th, 25th, 27th, and 28th. The afternoons will be devoted either to meetings of sections or to visits to local institutions on Sept. 24th, 25th, 26th, and 27th. The general meeting will be held on Sept. 26th at 9 A.M., and the closing meeting on Sept. 29th at 10 A.M. In the evening there will be a reception by the municipality at the Rathaus

August 7th and it was resolved that the Lord Mayor and the Deputy Mayor should be requested to ascertain the terms and conditions on which the corporation could acquire the estate and to negotiate for its purchase if the council and Local Government Board approved. Manchester, like other large towns, grows larger and larger, and takes into itself one green oasis after another, so that the uninterrupted succession of bricks and mortar, with chimneys, each one adding its contribution to the overhanging cloud of smoke, is ever extending. It would be a misfortune if this opportunity of obtaining so extensive and valuable an open space, a true "lung," for the city were lost. It would be of untold value in the future on the score of health. Of course, the question of cost is important, but long-suffering ratepayers do not always look on both sides of a question. They forget the advantages that would accrue to the city in the diminution of sickness, and so of expense, that would be sure to result if the Platt Fields were kept as an open space instead of being covered with dwellings.

Scarlet Fever at Dukinfield.

Rather a serious outbreak of scarlet fever has occurred at Dukinfield. At least 30 cases were reported a week ago. With the view of checking any further spread of the disease the local elementary schools are to be cleansed and disinfected. A similar outbreak took place some months ago and on that occasion Mr. J. R. S. Park, the medical officer, said there was no evidence, in his opinion, that the infection was conveyed by the milk- or water-supply.

Underfed and Badly Clothed.

Dr. Meredith Young, the medical officer of health, has been making investigations as to the feeding of the children attending the Stockport schools. He reports that 338 children in the town's schools are underfed and urges "the authorities to provide against this state of things." But he adds that "the question of clothing, and particularly of footwear, is of more importance to the health of such children than feeding," and he goes on to say that "if there be any funds that can be diverted in this direction I feel sure it would improve the health and physique of the children far more than any feeding experiments." The consideration of the remedy for this state of things, important as it is in its bearing on the future soundness and well-being of the race, would touch too closely on socio-political questions for these columns, but one thing stands out prominently, which is that the natural dependence of the children on the parents and the responsibility of the parents for the care and up-bringing of the children seem to be more and more lost sight of. The effect on the latter is, of course, to lessen the feeling of parents that they have duties towards their children and to loosen family ties. No doubt in a very large proportion of cases the vice of drunkenness or some other form of self-indulgence cripples the family exchequer and lowers the family morale. We seem to be approaching the age, if not of incubators, of artificial mothers for the nation.

£10,000 Maximum.

The University of Manchester does not appreciate the £10,000 maximum fixed by the Treasury in the place of the grant of £12,000, which had been received so long that it had come to be looked upon as income to be depended upon. It is said that no slur on the University is intended, but by the public it will be understood as a snub and will inevitably tend to lower the prestige and the prosperity of an institution which confessedly has adopted and maintained a high standard of efficiency and does not desire to be penalised by the crippling of its resources.

Lancashire Asylums Full.

At Clitheroe it was reported at the meeting of the board of guardians the other week that a certified lunatic inmate was still in the workhouse as no place could be found for him in an asylum. The five Lancashire asylums had been applied to but they were all full. The man was ill and scarcely fit to be removed, but if moved it would have to be to a Yorkshire asylum, and he would have to be certified by a Yorkshire authority. This is an unfortunate position for a self-respecting county.

August 13th.

CENTRAL MIDWIVES BOARD.—At the examination of candidates held by this board on August 1st there were 243 candidates examined, of whom 200 passed, being a percentage of failures of 17·7.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Development of School Children in Glasgow.

Dr. W. Leslie Mackenzie and Captain A. Foster have been engaged investigating for the Scotch education department the statistics amassed by the Glasgow school board as to the physical condition of the children attending school. For purposes of investigation the 73 schools were divided into four social groups. Group A included 26 schools in the poorest districts; Group B 27 schools in the poor districts; Group C, 11 schools in districts of a better class; and Group D, nine schools in districts of a still higher class, and including four out of the five higher grade schools in the city. Under all the groups about 73,000 children have been examined. In Group A 19 per cent. of the children resided in one-roomed houses and proportionately the grouping followed is confirmed by the distribution of one-, two-, and three-roomed houses. As to the general results of the inquiry, it is found that at each age from five to 18 the average weight of the children is uniformly below the standard of the anthropometrical committee of the British Association. As regards height, up to the age of 14 years the children, both boys and girls, are distinctly below the standard, while from the age of 15 years there is considerable variation, apparently owing to the small number examined above that age. There is, however, one exception: the children aged five years in Group D are in weight practically identical with the standard and in height are a shade over it. The boys in Group A fall very much below the standard. At the age of 10 years their average weight is 10 8 pounds below the standard and the average height 2·8 inches below the standard, and at 13 years the average is 11 1 and 3·1 below the standard respectively. With regard to the girls the facts are practically parallel. The graduation in height and weight from the poorest group to the best group is very striking. As surely as a child comes from Group A he or she is likely to be smaller and lighter than the children from Group B, and so on. The average weight of the one-roomed boy is 52·6 pounds, of the two-roomed 56·11 pounds, of the three-roomed 60·6 pounds, of the four-roomed and over 64·3 pounds. The respective heights are 46·6 inches, 48·1 inches, 50 inches, and 51·3 inches. Only one conclusion is possible —namely, that the poorest child suffers most in nutrition and growth. It cannot be a mere coincidence that boys from one-roomed houses should be 11·7 pounds lighter on an average than boys from four-roomed houses and 4·7 inches smaller. In the case of girls, also, it is shown that those from one-roomed houses are on the average 14 pounds lighter and 5·3 inches shorter than those from four-roomed houses.

Supposed Case of Spotted Fever in Aberdeen.

Dr. Matthew Hay, medical officer of health of the city of Aberdeen, in his report to the town council for June says: "Towards the end of the month a case of suspicious head illness was reported from Torry and was at once removed to the city hospital and the usual disinfection and other precautions were taken. The early progress of the case in the hospital did not definitely reveal the presence of cerebro-spinal fever, but within the past few days the spinal fluid has begun to show the presence of the germ characteristic of this disease. There has been no similar illness either before or afterwards in the family from which the case was removed and so far the source of the illness has not been traced. The patient, who is a boy of 15 years, had not been out of Aberdeen for some months before he took ill."

Opening of the Fyvie Cottage Hospital.

THIS hospital, which has been closed for several months on account of repairs and improvements, was opened last week in the presence of a distinguished company which included Lady Leith of Fyvie, Colonel and Miss Lorna Burn, Mrs. Albert Leith, Miss Bennett and Miss Giffen, Fyvie Castle. The opening ceremony was performed by Lady Leith who was introduced by the Rev. Mr. Wauchope Stewart. Lady Leith referred to the generosity of Colonel and Mrs. Gordon in giving the hospital to Fyvie some 27 years ago and expressed the belief that with all the new improvements in bedrooms, operating rooms, bathrooms, together with substantial teak-wood floors, the place would be more useful and comfortable than ever. Dr. C. C. Greig (Bridgend), in proposing a vote of thanks to Lady Leith for her kindness in with the subsequent addition of oil of aniseed and syrup; or (2) the simpler method of dissolving the essential oils of wormwood, anise, and coriander in rectified spirit, adding sugar and water, and colouring with chlorophyll. Absinthe is seldom drunk in a hurry by a thirsty and preoccupied individual standing at the counter of a public-house. It has to be diluted by the consumer, and this may be done with various adjuncts which give some opportunity for the display of dexterity, just as in mixing a salad during dinner or peeling an orange at dessert. In connexion with this subject we may mention that a substance indistinguishable from the ordinary absinthe of commerce, in respect of colour, odour, taste, and so on, has been recently put on the market under a totally different name.

VACCINE-THERAPY.

WE publish this week the first part of a lecture delivered before the Harvey Society of New York by Sir A. E. Wright, which we trust will prove of service to many of our readers. It summarises the practical results achieved by his investigations in clinical pathology along a line of research which he has devised and perfected, and which promises to lay the foundations of a new and valuable branch of therapeutics. The portion of the contribution contained in the present issue summarises the various methods other than vaccine-therapy which have been adopted in the treatment of bacterial disease and proceeds to the discussion of the principles and *rationale* of the latter method, the machinery of immunisation, the questions of the composition of vaccines, and the estimation of their immunising effects by the method of determining the opsonic index. Next week we shall publish the more detailed description of the process of which this first part is an introduction; the second part will consist of Sir A. E. Wright's study of the "Curves of Immunisation" obtained by vaccination and other matters connected with the process, the therapeutic principles on which it is based, and the question of auto-inoculation with its artificial production for therapeutic purposes, and will conclude with a summary of the results that have been achieved by vaccine-therapy at the author's hands.

THE ACCOMMODATION OF THE NAVVIES EMPLOYED ON THE BROOKLANDS MOTOR TRACK.

Dr. Reginald A. Farrar has issued a report to the Local Government Board dealing with the accommodation of the navvies employed on the motor racing track recently constructed at Brooklands, and he makes it the occasion of some remarks on the subject of the accommodation of navvies engaged on large constructional works in general. He estimates the navvies of Great Britain to form a nomadic community numbering with their women and children 100,000, and points out that they are in some sense outside the range of action of sanitary laws. It is an interesting sign of the times that a class that passed successively from the construction of dykes and canals to that of railways should now find its occupation depending on the motor industry. The social condition of the navvy of to-day is, we hope, better than that of those employed on the construction of the first great railways of the last century, of which those who have read Smiles's "Life of George Stephenson" will remember a very graphic picture. Dr. Farrar's report, however, shows that their conditions of life are far from being satisfactory and that in the case in point a body of 1600 men were imported into a neighbourhood to carry out work that would last over some months without any provision being made for their lodging and without the provision of even a trustworthy water-supply. Dr. Farrar made a personal inquiry into the state of affairs and found that some 600 men had lodgings in the neighbourhood, but that many of these had to walk or cycle from four to seven miles [illegible] and from their work daily, and that these were only accommodated by an unhealthy crowding of the lodging-houses and cottages in the neighbourhood. About 500 navvies came in to work by train, many from London; the fares paid by the latter reduced their weekly wage of 24*s.* by 4*s.* 6*d.* About 300 more were "sleeping rough," i.e., on Weybridge Common or in such straw- and stack-yards and even hen-houses (Dr. Farrar, by the way, says hen-coops) as they could enter undetected. When the weather was inclement they fortified themselves (in their own opinion) against the night in the open air by half stupefying themselves with beer. The men themselves had constructed two rough shelters on the site of the works, but these, owing to their insanitary state, were destroyed by the contractors, who, moreover, made no attempt to replace them until after Dr. Farrar's visitation. It is only fair to state that when the facts of the injustice to the men and the nuisance to the neighbourhood were pointed out the contractors readily undertook the erection of a wooden shed with bunks accommodating 50 men and laid on a good supply of drinking water from the main. The contract was unlike many others for important works, as a large number of men were employed working in night and day shifts, and the work had to be completed in an exceptionally short space of time. There seems no doubt, however, that the contractors were morally responsible, before introducing over 1600 men of a rough class into the neighbourhood, for ascertaining whether adequate lodging accommodation existed and supplying any default. Dr. Farrar in his report draws attention to some of the difficulties of the subject, and suggests the advisability of an inquiry into the conditions of navvy life in general with a possible view to legislation in the matter. The dissemination of infectious disease by this class should alone serve to direct attention to it in the interests of the community, and it is only fair to an indispensable and hard-working body of men that the necessities and decencies of life should be assured to them.

THE MECHANISM OF ABDOMINAL PAIN.

Professor Lennander of Upsala read an important paper on abdominal pain, especially in connexion with ileus, at the recent annual meeting of the American Medical Association, which is published in the *Edinburgh Medical Journal* for August. His valuable researches on the subject of the mechanism of abdominal pain are now well known. He has found that abdominal pain is transmitted solely by spinal nerves—the phrenic, lower six intercostal, lumbar, and sacral. No abdominal organ endowed with the sense of pain is innervated only by the vagus or sympathetic nerves. Even a strong faradic current applied to the liver does not produce pain. Professor Lennander has cut through the gall-bladder so far as the cystic duct without causing pain, but when he tilted the liver or dragged upon the common bile duct, thus stretching the spinal nerves of the abdominal wall, pain was felt. The stomach, intestines, liver, and gall-bladder are not only without the sense of pain but also without the other three varieties of sensibility—the senses of pressure, cold, and heat. Professor Lennander has also found that the parietal peritoneum of the anterior abdominal wall possesses only the sense of pain and is devoid of the sense of pressure, cold, and heat. His observations are in favour of the specificity of the nerves of pain and of the view that the whole of the parietal peritoneum is provided only with nerves of pain—a condition previously known in the cornea. He believes that all abdominal sensations are transmitted only by the parietal peritoneum and its subserous layer, both of which are richly supplied with cerebro-spinal nerves. The irritability of the nerves of pain of the parietal peritoneum is much increased by slight peritonitis. Hence the movements of the stomach and intestines against the parietal peritoneum and the stretching of their mesenteries are felt as

Sir Otto Jaffe said that when in Belfast the veterinary surgeon was appointed a strange arrangement was come to, in so far as that official was partly responsible to the market committee and partly to the health committee. Mr. Matthew Hedley, F.R C.V.S., of the Board of Agriculture, Dublin, moved a vote of thanks, which was seconded by Mr. W. Dawson, M.R.C.V.S., to Professor Mettam and Sir John Byers for their addresses, and these gentlemen having acknowledged the compliment the meeting terminated with a vote of thanks to the chairman. The Lord Mayor, the Earl of Shaftesbury, telegraphed regretting his inability to be present but wishing the conference every success.

Cerebro-spinal Meningitis.

At the last meeting of the public health committee (August 1st) it was reported that, practically speaking, cerebro-spinal fever had ceased to exist in Belfast. In future, no returns, as have been given each week, will again appear, unless the disease should break out again. It is to be hoped the public health authorities will give a full account of the great epidemic that has occurred in Belfast, so that some advance in our knowledge of the disease may be made. It is quite apparent that the malady has simply in time worn itself out, and apparently nothing has been discovered throwing any light either on its infectiousness or on its treatment.

The Belfast Health Commission.

The report of the Belfast Health Commission will probably not be ready before the end of September and it is not proposed to issue an interim report.

The Riots in Belfast.

The riots in Belfast took such a serious turn on August 12th that the Riot Act had to be read and the military were ordered to fire twice with the result that two men and a woman were killed and four others received gunshot wounds. A very large number of soldiers, police, and rioters received wounds from stones, broken bottles, and batons; and it is well-known that many of the rioters, for fear of being detected, do not come to hospital, but are treated at their own homes. The surgeons at the hospitals have had a new experience in treating gunshot injuries.

Belfast Hospital for Diseases of the Skin.

From the report which was presented at the annual meeting of the friends and supporters of this charity, held on July 31st, it appears that 652 patients were treated during the past year, of whom 31 were intern. There is a debt of £107. A new extern department and electric department, equipped with instruments and appliances of the most modern and approved type, have been added to the hospital. The Finsen light and x ray treatment, available now in this institution, will compare most favourably with that of any other similar hospital.

August 13th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Senile Atrophy of the Brain.

AT the Hospitals Medical Society on July 10th M. Pierre Marie exhibited two brains from old people which showed typical physiological senile atrophy, characterised by diminution in the volume and weight and by enlargement of the sulci separating the convolutions. Depressions and hollows could be made out on these brains such as have been wrongly considered to be lesions, and on one of them there is a depression with a brownish colouration which resembles an old hæmorrhagic focus at the level of the third left frontal convolution. The brain has the exact appearance of one of the two on which Broca constructed his theory of aphasia.

High Frequency and High Tension Sparks in the Treatment of Cancer.

At the Academy of Medicine recently M. de Keating-Hart said that he has tried treating cancer by the passage through the tumour of powerful sparks emitted from an Oudin's resonator. The results he has obtained have been the suppression or the relief of pain after a transient sensation of burning and the frequent arrest of hæmorrhages. The later effects, varying with the length of the sittings and the more or less advanced state of the disease, are marked by a diminution in the growth of the tumour and an improvement in the general condition of the patient.

Prognosis in Idiocy.

At the annual meeting of the Society of Hypnotism (Hypnologie) and Psychology M. Voisin expounded his views on the prognosis in idiocy; he considers that complete idiocy, whether congenital or acquired, is capable of improvement. Contrary to the general opinion, acquired idiocy is the graver form and the idiot children with regular features and very few signs of degeneracy are refractory to training; some external cause has apparently come definitely to interrupt their psychical development. On the other hand, children born with even very marked stigmata of degeneration are capable of some intellectual development.

The Pathology of Moveable Kidney and of Visceral Ptoses.

At the Academy of Medicine on July 23rd M. Reynier opposed the opinion of M. Lucas-Championnière that moveable kidney is caused by enteroptosis. He considered that the two affections are often connected but that they can occur independently; they are symptoms of a common cause which results from a primary functional disturbance in the nervous system. The tone of the abdominal musculature, in fact, depends on the nervous system, and it is the loss of this tone that causes the various ptoses. In the light of this etiology it is not astonishing to observe in patients suffering from these conditions mental and sensory phenomena out of all proportion to their lesions. The treatment of all these symptoms consists in the treatment of the moveable kidney either by a well-done fixation or the wearing of a suitable corset for the particular case.

The Pathological Significance of Shrinking of the Gums.

At a meeting of the Pathological Society M. Ferrie has described a form of shrinking of the gums observe in persons of advanced years and generally in those wit a tendency to calcification (of arteries), which is sufficiently distinct to be described as a clinical entity under th name of Fauchard's disease. This shrinking appears eve in subjects whose teeth have been cleared of tartar. Bacterial growth occurs in the recesses between the gum and teeth, followed by destruction of the periosteum surrounded by the gum, secondary alveolar necrosis, and shedding of the tooth, after which the trouble clears up as the recesses at the bottom of which the bacteria grew are destroyed. M. Ferrier attributes this shrinking of the gums to the contraction in the calibre of an arteriole; in other words the commencement of a local atheroma. The loss of resistance in a badly-nourished region is an established fact The correctness of this view is corroborated by the fact that "decalcifying remedies" have a marked preventive action on the process of the shrinking. The condition affords the practitioner an early sign of atheroma and a very useful indication for the employment of its proper treatment, and at the same time it may offer an explanation of other symptoms that the patient may present.

A Departmental Hospital for Villejuif.

The general council, on the motion of M. Roussel, has consented to the purchase of land for the erection of a departmental hospital for old people at Villejuif. The contract for building works is to be put up for tender. The furnishing will be given as much as possible to workmen's associations. The sum required will be 4,285,000 francs. The State will be asked for a subsidy.

Urinary Lithiasis and Tuberculosis.

At the Chirurgical Society M. Pousson recently made some observations on the coexistence of lithiasis and tuberculosis. He considers that in patients confined to bed for a long time for various tuberculous affections, especially those of bones, concretions of urates or oxalates are frequently formed in the kidney and more rarely in the bladder. This tendency to calculus formation is readily explained by the over-production of urates in these resting and over-fed patients. Secondary calculus concretions, nearly always phosphatic, are not rare in the kidneys, though they occur more often in the bladders of patients suffering from a bacterial infection in the stage of destructive suppuration. Besides these two classes of lithuric tuberculous subjects there is a third. This consists of patients who have undergone nephrectomy for tuberculous kidney disease and subsequently pass large quantities of sand in their urine, although they had passed none before the operation.

the association has withdrawn its cards and now confines itself to the completely praiseworthy function of aiding necessitous persons to purchase spectacles by means of grants. We wish to draw attention to a letter which appeared in the *Times* of August 12th, signed by Lady St. Helier, chairman of the executive committee of the association, and two other members. It is pointed out that some hospitals have, and others have not, adopted the reduced rate now in force at the Royal London Ophthalmic Hospital and approved by the Metropolitan Hospital Sunday Fund. The Royal Southwark Eye Hospital has arranged that the reduced prices should be charged to children only, adults still paying the higher rate. In other cases the higher rate is charged to all. We concur with Lady St. Helier and her colleagues in hoping that the public notification of this anomaly may lead other London hospitals to fall into line with the Royal London Ophthalmic Hospital.

EPIDEMIC CEREBRO-SPINAL FEVER.

SPORADIC cases of epidemic cerebro-spinal fever continue to be reported from widely separated districts, but the notifications are obviously diminishing. In Scotland during the week ended August 10th there were four deaths from this cause registered in Glasgow, two in Edinburgh, two in Leith, one in Greenock, and one in Perth. In Glasgow the weekly report issued on August 9th showed that there were at that time 44 cases under treatment. In Belfast during the week ended August 10th there were three deaths registered as being due to this cause.

SWISS SANATORIUMS FOR CONSUMPTIVES.

IN THE LANCET of July 2nd, 1904, p. 47, we gave some particulars of the cost of various Swiss sanatoriums, quoting some figures prepared by Dr. F. Schmid, president of the Swiss Committee for Combating Tuberculosis. This gentleman has just published his report for 1906 which contains some interesting details, and our Swiss correspondent writes: "Dr. Schmid refers to the nine sanatoriums which receive indigent patients (Volks sanatoria). They contain 671 beds, 114 of which are reserved for children. They are situated partly in the lowlands at an altitude of from 400 to 500 metres, partly in subalpine (from 800 to 900 metres) or Alpine districts (from 1000 to 1660 metres). The amount of air space which each patient has in the bedrooms varies from 20 to 50 cubic metres (from 16 to 20 in the sanatoriums for children). There is ample provision for conducting the open air treatment in the case of every single patient. The bedrooms and general sitting-rooms are well ventilated throughout. All the establishments are heated by radiators (Zentralheizung) and are lighted by electric light. The Zürich sanatorium at Wald and the sanatorium at Malvilliers (in the canton of Neuchâtel) alone are lighted by acetylene gas. The sputum is mostly disinfected by steam. Dr. Schmid made a special investigation to find out the average cost of erection of a sanatorium of about 100 beds in Switzerland. He comes to the conclusion that such a sanatorium, including the building plot and gardens, should not cost more than £220 per bed in the lowlands and £240 in the Alps, where the extra expense for constructing roads is considerable. These sums compare very favourably with those spent on similar sanatoriums in other countries. £300 are spent in Germany (Alland), £400 in America (Reception Hospitals, New York), the same amount in Sweden, £500 at Bligny (near Paris), £700 at Frimley (England), and from £530 to £880 in Russia. Dr. Schmid reports that the expense of erection of the four largest Swiss sanatoriums with from 90 to 120 beds amounts to £220 per bed, whereas in the case of small sanatoriums this sum rose to £310. The inclusive daily expenditure, without reckoning the interest on the capital expended for erection, amounts to 2·20 francs in the Bernese sanatorium at Heiligenschwendi and to 4·45 francs in the Basle sanatorium at Davos Platz, an average of nearly 3*s.* a day. In Germany this sum varied in five Hanoverian sanatoriums from 2*s.* 10*d.* to 3*s.* 10*d.* per diem."

THE VENTILATION OF FACTORIES AND WORKSHOPS.

A VALUABLE report issued recently under the auspices of the Departmental Committee appointed to inquire into the Ventilation of Factories and Workshops has been prepared with a view chiefly of furnishing some general guidance as to the application of fans to the ventilation of factories and workshops. It would appear that serious mistakes are frequently made in the design of ventilating fans owing to a want of knowledge of elementary principles. The purpose of the report is to set forth the essentials of the efficient ventilating installation, and it is to be hoped that owners and managers of factories and workshops who are not already familiar with the principles involved will fall into line with the excellent suggestions laid down. The report bears the signatures of Dr. John Scott Haldane, F.R.S.; Mr. E. H. Osborn, the engineering adviser to the Chief Inspector of Factories; Dr. James Ritchie, reader in pathology at Oxford; and the secretary, Mr. C. R. Pendock, inspector of factories for the Bristol district. The last-named gentleman has also prepared an appendix which contains a large number of detailed illustrations and descriptions, together with the results of experiments carried out for the committee on the proper arrangement of branch ducts and other apparatus connected with ventilation. The committee points out, seeing that the circumstances in which fan ventilation needs to be applied vary greatly in different rooms and different processes of manufacture, the necessity of carefully considering the special conditions requiring to be dealt with in each individual case. In all cases of doubt it is desirable that competent skilled advice should be obtained and that only such firms as are known to have at their disposal the requisite knowledge and experience in regard to fan ventilation should be employed. There can be no doubt that the adoption of the carefully drawn-up suggestions in this report would greatly mitigate, if not reduce altogether, the serious mischief caused to health by the inhalation of the dust evolved in certain trades.

THE CHURCH OF ENGLAND MISSION TO HOP-PICKERS.

WE have received the annual report of the Church of England Mission to Hop-pickers, accompanied by an appeal for help in the conduct of its annual campaign which will shortly open. The mission was founded 30 years ago and has been productive of the greatest good in the performance of its evangelistic, medical, and social work amongst a very low grade of the community. In a leading article in our issue of May 4th[1] we referred to the extremely interesting report on the accommodation provided for the hop-pickers which was made to the Local Government Board by Dr. Reginald A. Farrar; in this he described the arrangements that have been made by some of the larger growers to provide decent accommodation for the pickers. We may now quote his words in the report which deal with the work of this mission: "Credit for improvement in the condition of hop pickers is largely due to missions. It is generally agreed that there has been of recent years, owing to the influence of missionaries, a notable decrease of drunkenness among hop pickers, and this in itself conduces to a higher standard of decent living. Apart from the religious work of the Church of England Mission to Hop Pickers, the social work done by this society does much to promote the comfort and welfare a course of operations on the cadaver. This work is carried out with the personal assistance of the teacher, and in this manner a competent knowledge can be obtained. With regard to gynæcological operations, the best way to secure any return for the trouble and expense of studying at Budapest is to pay for a course of instruction under one of the chief assistants of the gynæcological surgeons, and this secures a welcome in the operating theatre. The amount of material in the hospitals of Budapest attracts a large number of students; but it is well for foreigners to remember that much time can be saved by careful selection of the methods of study.

---

[1] THE LANCET, May 4th, 1907, p. 1237.

Myopia in Hungarian Schools.

At a recent meeting of the Hygienic Society a report was read on an inquiry into the subject of myopia in Bihar county. About 2500 children were examined and the results of examination of the various school classes were tabulated. In the first school class the cases of myopia amounted to 12 per cent.; in the second the percentage was 8, in the third 4, in the fourth 3·3, in the fifth 1·8, and in the sixth 0·2, showing a gradually increased percentage with lengthened period of study. The reporter said that the tables demonstrated the great influence of the school in the development of myopia. For a comparison he also examined 560 pupils in private schools, where the well-to-do people send their children to learn. He found that there the percentage of myopia was only 1·4, a proof that the unfavourable conditions prevalent in public schools were the cause of the eye trouble. He observed very little follicular inflammation and never met with trachoma. There was one case of congenital cataract in a boy of 11 years who had been looked upon as idiotic, the ophthalmic affection having completely escaped the notice of the teachers. The school buildings were inspected from a hygienic point of view and condemned. Although newly constructed the seats were of an old-fashioned type and compelled a faulty position of the children sitting on them. The class rooms were comparatively dark, only one-third of the area of one large room receiving direct light from without. The heating of all the schools was also very imperfect and on account of the street noises the ventilation had to be subordinated to the comfort of the occupants of the class rooms.

August 10th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Assistant Army Surgeons.

THE recent examination of applicants for the position of assistant surgeon in the army demonstrates the disadvantages under which the Medical Department labours on account of the failure of Congress to approve of measures of reform which would place that service on the same basis as other branches. There is nothing now in the medical service which invites young surgeons to enter it. The rank of the surgeon is inferior and the opportunities for promotion are few and far between. Of 33 candidates who were invited to appear and take the examination only 11 responded. Of these 11 who took the entire examination seven were found qualified, an unusally large proportion of successful candidates in comparison with past experience. There are now 31 vacancies in the junior grade of the Medical Department and the prospects of filling them are less favourable than for many years past.

Prohibiting Publicity of Treatment of Sexual or Menstrual Disorders.

The Legislature of the State of Colorado has passed an Act to protect the public morals by prohibiting the giving general publicity to treatment and devices for the cure or prevention of sexual or menstrual diseases. The law provides that it shall be unlawful for any person, association, partnership, or corporation to circulate, disseminate, spread, print, publish, or cause the circulation, dissemination, spreading, printing, or publication of any public advertisement, announcement, publication, notice, or information of the treatment, alleviation, palliation, cure, or prevention of any sexual or menstrual disease, weakness, or condition. But this Act shall not prevent such publication or dissemination of any such advertisement in exclusively medical publications and publications designed and circulated among dealers as trade journals not designed for public inspection.

Progress in the Care and Prevention of Tuberculosis.

It is a matter of surprise and congratulation that the prevention of tuberculosis and the better care of those suffering from that disease have taken such a deep and abiding hold upon the public mind and conscience. Throughout the entire United States the common people are moving with a determined purpose of exterminating the pestilence. It is interesting to notice the great variety of methods pursued to accomplish this object. In the State of Missouri societies for the prevention of tuberculosis are being formed in every town and all of these societies will be under the direction of a central organisation in order to secure harmony in their operations. The intention of the promoters of this scheme is to unite the entire people of the State in the common object of exterminating the disease in that section. In the State of Maryland a travelling "Tuberculosis Exhibit" has been organised for the general education of the people in the most approved methods of prevention and relief of tuberculosis. Besides showing charts, photographs, pathological specimens and models, the association, which has the management of the exhibit, will provide for lectures with stereopticon views where lanterns are available. In the State of Pennsylvania the immense public forests are about to be given up to the care and treatment of the tuberculous poor, the State providing simple "shaks" at the rate of a dollar per week. In the city of New York an abandoned ferry boat has been moored at a dock and made a very simple day-camp fo consumptives. There is a trained nurse in charge with a regular visiting staff of physicians; the number of patient is 50 and the results obtained are in every way most satisfactory. These instances of novel methods of combating the common enemy might be multiplied indefinitely.

Military Hygiene in Public Schools.

In a prize essay Colonel Hoff, of the United States Army makes the suggestion that the American Red Cross shoul exert its influence to have the elements of military hygien taught to boys in the public schools. He states that suc teaching would not add much to the course, nor would make any intellectual demand beyond that which could b met by an average student. Its value would lie in teaching the student how to take care of himself in the field what to do and what to avoid, and would give him th rules of right living and the reasons under the stress of campaign. Boys who have learned these facts in early lif would enter the military service so enlightened in regard t the best methods of preserving good health that the ordinar camp diseases would disappear. The same writer advise that the colleges and universities should be required t recognise these hygienic studies in their curricula. Especiall is this true of the medical colleges which should make a adequate knowledge of military hygiene obligatory not onl for the degree in medicine but for the State licences practise medicine. It seems to Colonel Hoff that it peculiarly the mission of the Red Cross to secure the refor in education which he proposes.

The Insurance Fee Question.

The final action of the American Medical Association o the question of fees for medical examination in insuran companies was to commit the subject to the State an county societies for such action as they may deem wise ar proper. Heretofore, each physician was to fix the fee each individual case as he might deem proper and the resu was that there was no uniform charge on the part of th profession for these services. The insurance companies too advantage of this condition and succeeded in reducing th fee in many instances to a ridiculous figure. The rece action of the association makes it incumbent for loc medical societies to fix the fees, and thus there will uniformity of rates in each State or county.

August 3rd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Hospital Affairs.

THE annual meeting of the friends and supporters the Queen Victoria Homes for Consumptives of New Sout Wales was held on May 27th, the State Governor presidin In the report it was stated that at the King's Tableland Home the daily average number of beds occupied was 45 and that relating to measles showed at a glance that there had been no instances of that disease for more than seven years. He was therefore prepared to advise school closure on the appearance of the first case of measles in that particular village. From the outset it was recognised on all hands that the voluntary element was to be the dominant factor; there was to be no threat of legal proceedings; moral suasion was the order of the day. Parents in general were given to understand that they at all times had direct access to him and that their suggestions would be welcomed. His own views on the subject of prevention of contagious and zymotic diseases among scholars were that detailed medical examination was unnecessary; while a cursory glance was usually sufficient to detect actual cases it could not be the means of stamping out the disease. The remedy lay rather in the provision of improved school furniture and school equipment; for each scholar nothing less than a separate desk and separate books, a separate drinking cup, and a separate peg for his clothing; while as for school buildings the tendency will have to be in the direction of better lighting, better ventilation, and more suitable offices, for he had in his mind the vivid picture afforded by the repeated inspection of some 60 rural and semi-rural schools. As to disease of the special senses, eye and ear, no doubt the appointment of inspecting medical officers would in course of time bring to light the large amount prevalent in rural as in other schools, when treatment and alleviation would naturally follow. The general adoption of any scheme of medical supervision would disclose the danger of the unsupervised private schools to which those parents who were offended by any scheme for medical supervision of their offspring would undoubtedly send their children. If such parents said that they considered the State medical supervision of their children as undermining of their own parental authority and a replacement of parental responsibility, it could be pointed out that in any case the parent had the last word in the matter. For as the law now stood the parent prevailed; he need not carry out medical advice or treatment even when tendered. All recent legal decisions confirmed that. No scheme of medical supervision could be of avail which did not recognise the powerful authority of the head teacher with his scholars and his influence with the parents; emphatically was that the case with infant schools, the head mistresses of which appeared to be in the position of guide, counsellor, friend, and confidante to those parents whose little ones were committed to their care. If at any time difficulty was experienced in the inception of any scheme perhaps it would be as well to hasten slowly and to make a beginning with the infant school, whose head mistress would be found to be "a power in the land"; then progress might be made through the lowermost standards, reaching last of all the girls of the highest standard. He made a point of that for the reason that he had found that a large proportion of the girls in the sixth and seventh standards were expected to look after themselves, the parents disclaiming responsibility. Further, the girls of those standards regarded the suggestion of medical examination as a slur, the actual inspection an indignity the memory of which would linger with them, "soon to be sent out into the world to earn their own livings." He might add that towards the end of the experiment the Gloucestershire branch of the National Union of Teachers held a meeting at which that method of medical inspection was discussed and approved of.

"*The Personal Health Ticket in Schools.*"

This was the title of a communication from Dr. S. BERNHEIM and Dr. LE DIEUPART of Paris, who had organised a distribution of circulars to medical inspectors of schools containing inquiries on the health of the scholars. They declared in common with the majority of their professional brethren that an inspection, even when strictly and carefully made, was not sufficient to protect the pupil, his schoolfellows, and teachers. It was indispensable that every person, whether child or adult, in habitual attendance at a school, a class, or a lycée should have a personal health ticket. This record would be quite confidential and would be accessible only to the visiting medical officer or to the relatives of the person concerned. If the child were removed from one school to another the ticket would be passed on to the medical officer of the latter school either by the family or by the first medical officer. That ticket would be of importance for a child by showing the state of his health and the capacity for work. In that way tasks incompatible with his health would not be required of him, as happened too often, and a system of education would be arranged for him consistent with the bodily and mental powers. In case of infectious disease or threatening tuberculosis the child would not be allowed to attend school so that he might recover and might not infect his schoolfellows. At a later period this personal health ticket would be equally useful to the adult, who would be able to present it when the time for military service arrived and might in that way be saved a great deal of trouble. That record would be for him an official and authenticated document. Dr. Bernheim and Dr. Dieupart had observed among the teachers a great many tuberculous persons who were a constant danger to the children among whom they worked. For them also the sanitary health ticket was indispensable. Finally, they thought that the sanitary inspection of schools would be more effectual, because the medical officers would for that purpose have to keep books which would require to be regularly brought up-to-date. The adoption of the proposed scheme would involve an immediate and thorough improvement in the sanitary inspection of schools.

A paper on

The Floor as the Principal Factor in Contagious Diseases in Schools.

This subject was contributed by Dr. BERNHEIM. After insisting on the importance from a sanitary point of view of all parts of the structure of a school building Dr. Bernheim declared that hygienically the floor was the most important thing of all. In proportion as it was of homogeneous structure and easily cleaned and repaired, so was the health of the establishment good. The worse the condition of the floor of a class-room the more sickness there was among the pupils. Dr. Bernheim had examined the dust from well-worn floorings in old buildings and he had found in it many virulent bacteria. He strongly recommended certain floor materials, having a basis of asbestos, as cheap, durable, and easy of application.

The Medical Inspection of "Public Schools."

Dr. CLEMENT DUKES (physician to Rugby School), dealing with "a record of the physical examination of 1000 boys at their entrance on public school life," said that it was somewhat depressing to register in the twentieth century the large number of acquired preventable deformities which were presented by the most favoured class of boys in Great Britain. (We are publishing Dr. Dukes's valuable paper in an early issue of THE LANCET.)

Dr. T. DYKE ACLAND (London) emphasised the need for the inspection of all residential secondary schools in matters relating to sanitation and hygiene. There was a tendency to limit the work of the school medical officer to the comparatively unsatisfactory work of attendance on the sick and to overlook that far more important branch of his work—preventive medicine—by which sickness might be prevented and the better development of the boys under his care secured. That public schools were in various ways behind the times seemed to be due in the first instance to their being practically free from competition. How many, he asked, of our public schools would pass the ordeal if inspected on the lines required for public elementary schools? All endowed schools, two only excepted, were liable to inspection; two or three had already voluntarily applied for inspection. It was to be hoped that the time was not far distant when all residential schools would be subject to independent criticism and report; and further, would be required to publish annually what might be called a "health audit."

In the course of the work of the Congress Dr. OEBRECKE (Breslau) urged that the school medical adviser should not be in private practice, but that his work should be that of supervising. He dwelt upon the desirability of coöperation between the medical man, the teacher, and the parent.

Dr. OUNTZ (Wiesbaden) maintained that the work of the school medical adviser should be to notify and prevent sickness or disease and to look after the hygiene of the school and class rooms, while the medical treatment of the children themselves should be left to the family practitioner.

The Attitude of Parliament.

Mr. W. J. WILLIS BUND (chairman of the Worcestershire education committee) presented some practical administrative hints with regard to the medical inspection of school children provided for in the Bill now before Parliament. He said that ratepayers protested loudly against the appointment of new officers at high salaries, but if a staff insufficient in number and qualifications were appointed it

Ernest Elkington, University of Birmingham; Abraham Solomon Erulkar, Guy's Hospital; Maud Frances Forrester-Brown, London (Royal Free Hospital) School of Medicine for Women; John Torbet Smith Gibson, St. Mary's Hospital; Marjory Winifred Godden, London (Royal Free Hospital) School of Medicine for Women; Thomas Chivers Graves, Royal Veterinary College; Olive Gertrude Mary Gray, London (Royal Free Hospital) School of Medicine for Women; Geoffrey Hadfield, Plymouth Technical Schools; Thomas Edwin Hammond, Cheltenham College and private tuition; Cecil Rhodes Harrison, St. Mary's Hospital; Philip Henry Henson, Epsom College; Bernard Whitchurch Howell, St. Bartholomew's Hospital; Frederic James Humphrys, St. Thomas's Hospital; John Cecil Jefferson, Victoria University of Manchester; Cecil Meredyth Jones, Cardiff Municipal Secondary School and private study; William Henry Kauntze, Victoria University of Manchester; Skene Keith, Guy's Hospital; Andrew Carey McAllister, King's College; John Finlayson Mackenzie, Guy's Hospital; Melville Douglas Mackenzie, Epsom College; Thomas Hartley Martin, University of Liverpool; William Matthews, Guy's Hospital; Philip Henry Mitchiner, St. Thomas's Hospital; John Forbes O'Connell, Epsom College; Charles Cyril Okell, private tuition; William David Owen, University College, Cardiff; Donovan Blaise Pascall, St. Bartholomew's Hospital; Richard Douglas Passey, Guy's Hospital; Cecil Joseph Herbert Pearson, London Hospital; William Agard Pocock, Cheltenham College; Arthur Leslie H. Rackham, Epsom College; Sidney Bertram Radley, Victoria University of Manchester; Noel Ravenchil Rawson, London Hospital; James Ewen Robertson-Ross, Epsom College; Samuel Pryce Rowlands, University College, Cardiff, and Tutorial School, Penarth; George William Shore and Sidney Smith, King's College; Douglas Benham Spence, Epsom College; William Steuart, St. Bartholomew's Hospital; Robert Swyer, London Hospital; Albert Joseph Tonkinson, West Bromwich Municipal Secondary School; Thomas Burges Welch, St. Mary's Hospital; Eva Muriel White, Bedford College; Cecil Leonard Williams, Plymouth Technical Schools; Thomas Davies Williams, London Hospital; and Edward Alfred Wilson, Middlesex Hospital.

Inorganic Chemistry and Experimental Physics.—Oscar Newrick William Brown, King's College and Westminster Hospital; George Rowland Dobrashian, Bootham School; *George Edward Genge-Andrews, Guy's Hospital; *Douglas Medlicott Gibson, St. Thomas's Hospital; *Melville Hocken, London Hospital; Richard Orthin Hilton Jones, Guy's Hospital; *James Duncan Lyle and *Harrold Winnock Parrott, London Hospital; *Cresswell Lee Pattison, St. Mary's Hospital; George Harold Pearson, London Hospital; Frederick Harold Rees, Cardiff Intermediate School; Arthur Leonard Shearwood, Whitgift Grammar School, Croydon; William Simpson, St. Bartholomew's Hospital; Winifred Christian Squires, London (Royal Free Hospital) School of Medicine for Women; Harold Eustace Thorn, St. Paul's School; and Frederick Edward Saxby Willis, Dulwich College.

Inorganic Chemistry and Biology.—Arthur Ernest Bullock, St. Paul's School; ‡Charlotte Grace Judge, London (Royal Free Hospital) School of Medicine for Women; Edward Athol Clarence Langton, Epsom College; Claude John Burgoyne Pasley, King's College and Westminster Hospital; and ‡Walter Salisbury, University College, Bristol.

Experimental Physics and Biology.—Edward Smith Abraham, University College, Bristol; Edward Bach, University of Birmingham; Henry Washington Batchelor, Berkhampsted School; Raymond Brewitt-Taylor, St. Bartholomew's Hospital; John Lloyd Davies, University College, Cardiff; John Yerbury Dent, King's College; Joseph De Silva, St. Mary's Hospital; Pattie Ruth Elliott, University College, Nottingham; Abel Evans, University College, Cardiff; William Stanley George, Guy's Hospital; Mary Isabel Hemingway, Ladies' College, Cheltenham; John Higgins, London Hospital; Charles Eric Sweeting Jackson, St. Mary's Hospital; George Hattersby Jameson, Victoria University of Manchester; Gwilym Rhys Pennant and Thomas Harold Phillips, University College, Cardiff; Reginald Norman Porritt, Epsom College; †William Barwise Sanders, University Tutorial College; Aubrey John Colby Tingey, University of Liverpool; and James Vaughan-James, University College, Cardiff.

PART II.

Organic Chemistry.—George Stanley Applegate, University College, Bristol; Edward Alfred Barker, Guy's Hospital and University College, Bristol; Thomas Beaton, University College, Cardiff; Cyril Carlyle Beatty, London Hospital; Alured C. L. O'S. Bilderbeck, St. Bartholomew's Hospital; Sydney Guy Billington, University of Birmingham; Gilbert Alan Blake, Guy's Hospital; George Francis Bradley, London Hospital; Gertrude Brooks, London (Royal Free Hospital) School of Medicine for Women; Arthur Barrett Cardew, Middlesex Hospital; Albert James Clarke, St. Bartholomew's Hospital; Irene Nancy Clough, London (Royal Free Hospital) School of Medicine for Women; John Warren Clouston, London Hospital; John Henry Cobb, University of Sheffield; Ardeshir Koyaji Contractor, University College and Grant Medical College, Bombay; Frank Cook, Guy's Hospital; Herbert William Cooke, University College, Bristol; Arnold Charles S. Courts, University College; Herbert Davies, University College; James Anthony Delmege, Guy's Hospital; Gertrude Margaret Dobrashian, London (Royal Free Hospital) School of Medicine for Women; Thomas Peters Edwards, St. Bartholomew's Hospital; Basil Franklin Eminson and Ralph Franklin Eminson, Charing Cross Hospital; David Benjamin Evans, University College, Cardiff; Eric Alfred Charles Faran, Middlesex Hospital; James Maurice Foord, University of Leeds; James Rocheld Forrest, private study; William Charles Fowler, University College; Vincent Glendining, Guy's Hospital; Wilfrid Montague Glenister, St. Bartholomew's Hospital; Abdul Hamid Gool, Guy's Hospital; Alexander Keith Hamilton, University of Liverpool; Frederick Wood Hamilton, Middlesex Hospital; Reginald Gordon Hill, St. Bartholomew's Hospital; Robert Hamer Hodges, King's College, George Ashby Hooton, St. Bartholomew's Hospital; Herbert Leslie Hopkins, Guy's Hospital; Charlotte Leighton Houlton, London (Royal Free Hospital) School of Medicine for Women; Christopher Martin Ingoldby, London Hospital; James Moncrieff Joly, Cheltenham College and Guy's Hospital; Duncan Ince Jones, University College; Charles Dones Killpack, Guy's Hospital; Leon Levene and William Howard Lister, University College; Martin W. Littlewood, St. Thomas's Hospital; Joseph Howell Lloyd, private study; Gerald Roche Lynch, St. Mary's Hospital; Roy Kyffin Mallam, London Hospital; Geoffrey Marshall, Guy's Hospital; Henry Linnington Martyn, King's College; Pestanji Manekji Medui, University College; Charles Edward Hamilton Milner, King's College; Patrick John Monaghan, Guy's Hospital; Harold Arundel Moody, King's College; John Grimson Moseley, London Hospital; Clement Treves Neve, St. Bartholomew's Hospital; Alfred Arthur Edmund Newth, King's College; Joan Fraser Parker, London (Royal Free Hospital) School of Medicine for Women; Bernard Rayne Parmiter, Guy's Hospital; Hubert Charles George Pedler, University College; Sara Louisa Penny, London (Royal Free Hospital) School of Medicine for Women; James Potter, London Hospital; Camilo Antonio Prada, St. Bartholomew's Hospital; William James Aitkin Quine, private study; Edward Gordon Reeve, Guy's Hospital; George FitzPatrick Rigden, King's College and Westminster Hospital; Stanley Ritson, King's College; Ffrangcon Roberts, Epsom College; Russell Rodgers, Guy's Hospital; Frederic Sanders, London Hospital; William Henry Price Saunders, Epsom College; Edward Gustave Schlesinger, Guy's Hospital; Charles Frank Schuler, St. Thomas's Hospital; Emmanuel Prinald Scott and William Geoffrey Shaw, London Hospital; Francis Robert Bradley Skrimshire, St. Thomas's Hospital; Geoffrey Troughton Smith, Guy's Hospital; Reginald Gershom Sparkes, St. Mary's Hospital; Ernest Gerald Stanley, St. Bartholomew's Hospital; James Lennox Stewart, Guy's Hospital; Ludwig Siebert Benjamin Tasker, University College; Horatio Thomas, University College, Cardiff; Francis Richard Todd and John Tremble, St. Bartholomew's Hospital; Arthur Bayford G. Underwood, University College; William Henry Vincent, St. Mary's Hospital; Richard Trevor Vivian, St. Bartholomew's Hospital; Michel Demètre T. Vlasto, University College; Harry Bertram Walker, London Hospital; Joseph Stephen Wallace, University College; George Edgar Septimus Ward, Middlesex Hospital; Harold Percy Warner, Guy's Hospital; and Horace Harvey H. Vincent Welch, St. Thomas's Hospital; and Horace Richard Wilson, Dalston Technical College and Paddington County Council Technical Laboratory.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

A new course on school hygiene, including lectures, demonstrations, and practical work, has been arranged to begin on Oct. 16th at University College. The course will be given by Professor Henry R. Kenwood and Dr. H. Meredith Richards. It is designed to meet the requirements of school teachers, school lecturers, and those qualifying for school inspectorships and for school medical officers. A certificate of proficiency will be granted to those who qualify themselves.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Victor Schmieden has been recognised as *privat docent* of Surgery.—*Budapest:* Dr. Eugen Kollarits has been recognised as *privat-docent* of Neuropathology.—*Erlangen:* Dr. Oskar Schulz, *privat-docent* of Physiology, has been granted the relating to measles showed at a glance that there had been no instances of that disease for more than seven years. He was therefore prepared to advise school closure on the appearance of the first case of measles in that particular village. From the outset it was recognised on all hands that the voluntary element was to be the dominant factor: there was to be no threat of legal proceedings; moral suasion was the order of the day. Parents in general were given to understand that they at all times had direct access to him and that their suggestions would be welcomed. His own views on the subject of prevention of contagious and zymotic diseases among scholars were that detailed medical examination was unnecessary: while a cursory glance was usually sufficient to detect actual cases it could not be the means of stamping out the disease. The remedy lay rather in the provision of improved school furniture and school equipment: for each scholar nothing less than a separate desk and separate books, a separate drinking cup, and a separate peg for his clothing; while as for school buildings the tendency will have to be in the direction of better lighting, better ventilation, and more suitable offices, for he had in his mind the vivid picture afforded by the repeated inspection of some 60 rural and semi-rural schools. As to disease of the special senses, eye and ear, no doubt the appointment of inspecting medical officers would in course of time bring to light the large amount prevalent in rural as in other schools, when treatment and alleviation would naturally follow. The general adoption of any scheme of medical supervision would disclose the danger of the unsupervised private schools to which those parents who were offended by any scheme for medical supervision of their offspring would undoubtedly send their children. If such parents said that they considered the State medical supervision of their children as undermining of their own parental authority and a replacement of parental responsibility, it could be pointed out that in any case the parent had the last word in the matter. For as the law now stood the parent prevailed; he need not carry out medical advice or treatment even when tendered. All recent legal decisions confirmed that. No scheme of medical supervision could be of avail which did not recognise the powerful authority of the head teacher with his scholars and his influence with the parents: emphatically was that the case with infant schools, the head mistresses of which appeared to be in the position of guide, counsellor, friend, and confidante to those parents whose little ones were committed to their care. If at any time difficulty was experienced in the inception of any scheme perhaps it would be as well to hasten slowly and to make a beginning with the infant school, whose head mistress would be found to be "a power in the land"; then progress might be made through the lowermost standards, reaching last of all the girls of the higher standard. He made a point of that for the reason that he had found that a large proportion of the girls in the sixth and seventh standards were expected to look after themselves, the parents disclaiming responsibility. Further, the girls of those standards regarded the suggestion of medical examination as a slur, the actual inspection an indignity the memory of which would linger with them, "soon to be sent out into the world to earn their own livings." He might add that towards the end of the experiment the Gloucestershire branch of the National Union of Teachers held a meeting at which that method of medical inspection was discussed and approved of.

"The Personal Health Ticket in Schools."

This was the title of a communication from Dr. S. BERNHEIM and Dr. LE DIEUPART of Paris, who had organised a distribution of circulars to medical inspectors of schools containing inquiries on the health of the scholars. They declared in common with the majority of their professional brethren that an inspection, even when strictly and carefully made, was not sufficient to protect the pupil, his schoolfellows, and teachers. It was indispensable that every person, whether child or adult, in habitual attendance at a school, a class, or a lycée should have a personal health ticket. This record would be quite confidential and would be accessible only to the visiting medical officer or to the relatives of the person concerned. If the child were removed from one school to another the ticket would be passed on to the medical officer of the latter school either by the family or by the first medical officer. That ticket would be of importance for a child by showing the state of his health and the capacity for work. In that way tasks incompatible with his health would not be required of him, as happened too often, and a system of education would be arranged for him consistent with the bodily and mental powers. In case of infectious disease or threatening tuberculosis the child would not be allowed to attend school so that he might recover and might not infect his schoolfellows. At a later period this personal health ticket would be equally useful to the adult, who would be able to present it when the time for military service arrived and might in that way be saved a great deal of trouble. That record would be for him an official and authenticated document. Dr. Bernheim and Dr. Dieupart had observed among the teachers a great many tuberculous persons who were a constant danger to the children among whom they worked. For them also the sanitary health ticket was indispensable. Finally, they thought that the sanitary inspection of schools would be more effectual, because the medical officers would for that purpose have to keep books which would require to be regularly brought up-to-date. The adoption of the proposed scheme would involve an immediate and thorough improvement in the sanitary inspection of schools.

A paper on

The Floor as the Principal Factor in Contagious Diseases in Schools.

This subject was contributed by Dr. BERNHEIM. After insisting on the importance from a sanitary point of view of all parts of the structure of a school building Dr. Bernheim declared that hygienically the floor was the most important thing of all. In proportion as it was of homogeneous structure and easily cleaned and repaired, so was the health of the establishment good. The worse the condition of the floor of a class-room the more sickness there was among the pupils. Dr. Bernheim had examined the dust from well-worn floorings in old buildings and he had found in it many virulent bacteria. He strongly recommended certain floor materials, having a basis of asbestos, as cheap, durable, and easy of application.

The Medical Inspection of "Public Schools."

Dr. CLEMENT DUKES (physician to Rugby School), dealing with "a record of the physical examination of 1000 boys at their entrance on public school life," said that it was somewhat depressing to register in the twentieth century the large number of acquired preventable deformities which were presented by the most favoured class of boys in Great Britain. (We are publishing Dr. Dukes's valuable paper in an early issue of THE LANCET.)

Dr. T. DYKE ACLAND (London) emphasised the need for the inspection of all residential secondary schools in matters relating to sanitation and hygiene. There was a tendency to limit the work of the school medical officer to the comparatively unsatisfactory work of attendance on the sick and to overlook that far more important branch of his work—preventive medicine—by which sickness might be prevented and the better development of the boys under his care secured. That public schools were in various ways behind the times seemed to be due in the first instance to their being practically free from competition. How many, he asked, of our public schools would pass the ordeal if inspected on the lines required for public elementary schools? All endowed schools, two only excepted, were liable to inspection; two or three had already voluntarily applied for inspection. It was to be hoped that the time was not far distant when all residential schools would be subject to independent criticism and report: and further, would be required to publish annually what might be called a "health audit."

In the course of the work of the Congress Dr. OEBBECKE (Breslau) urged that the school medical adviser should not be in private practice, but that his work should be that of supervising. He dwelt upon the desirability of coöperation between the medical man, the teacher, and the parent.

Dr. CUNTZ (Wiesbaden) maintained that the work of the school medical adviser should be to notify and prevent sickness or disease and to look after the hygiene of the school and class rooms, while the medical treatment of the children themselves should be left to the family practitioner.

The Attitude of Parliament.

Mr. W. J. WILLIS BUND (chairman of the Worcestershire education committee) presented some practical administrative hints with regard to the medical inspection of school children provided for in the Bill now before Parliament. He said that ratepayers protested loudly against the appointment of new officers at high salaries, but if a staff insufficient in number and qualifications were appointed it

Friday, August 9th.

Vaccination (Scotland) Bill.

The Vaccination (Scotland) Bill was read a third time and passed.

HOUSE OF COMMONS.

Wednesday, August 7th.

An Irish Dispensary Appointment.

Mr. Vincent Kennedy asked the Chief Secretary to the Lord Lieutenant of Ireland to state why the Local Government Board refused to sanction the appointment of Dr. Clarke as temporary medical officer for the Bellananagh dispensary district; how near to this district did Dr. Clarke reside; had Dr. Clarke at present any dispensary; who had been in charge of this district for the past three months, and what appointments did he hold, distinguishing those which were temporary from the permanent appointments; and would this matter have his special attention in the interest of the sick poor of the district.—Mr. Cherry (the Attorney-General for Ireland) replied: The appointment of Dr. Clarke as temporary medical officer for the Bellananagh dispensary district was objected to on the ground that his residence was outside the dispensary district and was inconvenient for the sick poor. The nearest point to the dispensary district was about three miles and the most remote nine miles from Cavan where Dr. Clarke lives. The Local Government Board has not sanctioned the appointment of Dr. Clarke as medical officer for any dispensary district. Dr. Clarke has been acting as temporary medical officer for the Bellananagh dispensary district since June 18th last but without sanction of the Board. He has also been appointed as temporary medical officer of the Kilnaleck and Stradone dispensary districts, but the Board has had to object to these appointments on the same grounds. The guardians by their action in continuing to employ Dr. Clarke may render themselves liable to surcharge for any payments they may make for his salary. Dr. Clarke has further been appointed as temporary medical officer to the Cavan workhouse from August 7th to Sept. 4th and to this appointment the Board has given its sanction.

Thursday, August 8th.

Enteric Fever at Bulford Camp.

Mr. Long asked the Secretary of State for War whether he could state how many outbreaks of typhoid fever had occurred at Bulford Camp and at what intervals; how many cases had resulted fatally; and what steps he proposed to take to protect the lives of officers and men from the grave risks to which they were exposed.—Mr. Haldane replied: Since 1900 there have been 16 cases of enteric fever among the regular troops at Bulford—two in 1903, three in 1904, three in 1905, and eight in June, 1907. None of the cases were fatal. As regards the auxiliary forces, of whom 45,000 were encamped at Bulford in 1906, there were nine cases in the Honourable Artillery Company of which it is understood two proved fatal. Full investigations were carried out by specialist sanitary officers in the case of the outbreaks in 1904, 1906, and 1907, and though no definite cause for the origin of the disease can be traced, in each instance the available evidence pointed to the introduction of the infection from without and not to any defect in the camp area. The medical and sanitary arrangements of the camp are supervised by the principal medical officer of the Southern command and the administrative medical officer to the Tidworth district, who have the assistance of a specially qualified sanitary officer in dealing with the prevention of infectious disease amongst the troops.

Milk Carriage in Ireland.

Mr. Halpin asked the Vice-President of the Department of Agriculture (Ireland) whether he would inquire into the railway system for carrying milk, seeing that the railway van was at present the only means by which long-distant milk could be conveyed from the producer to the public; whether he was aware that in some cases the van was dirty and ill-ventilated, and that along with the milk were carried hides, carcasses of meat, and live fowls; and whether he would use his influence with the railway companies to have milk carried in pure milk vans.—Mr. T. W. Russell (in a written answer) replied: If by "railway van" is meant the guard's van the department is not aware that this is the only kind of vehicle by which milk is conveyed over long distances. The transit inspectors of the department have instructions to report any cases which come under their notice of milk being carried in dirty vehicles or with articles likely to taint it, and in any such reported cases the matter is taken up with the carrying company concerned. If specific instances are brought under the notice of the department they will have full inquiry made.

Monday, August 12th.

Medical Inspection of School Children.

The House in dealing on report with the Education (Administrative Provisions) Bill considered the clause with respect to the medical inspection of school children.

Sir Henry Craik moved an amendment that the local authorities should direct a medical inspection to take place where required by the Board of Education. The burden of carrying out a medical inspection was one which the Government should not place on the local authorities without taking a large share both financially and in scientific direction. If the Government were to press the clause forward let them bring forward a detailed scheme.

Mr. E. Cecil seconded the amendment.

Mr. McKenna hoped that the amendment would not be pressed. It was the intention of the Board of Education to establish a medical branch for the purposes of guiding the local authorities in the new work they would have to undertake. The formation of that branch had been occupying the attention of the Board for some time past. Its duties would be to collect information, collate it, and to give such instructions to the local authorities as would enable them to carry on their duties under the clause.

The amendment was negatived without a division.

Sir P. Magnus moved an amendment to give the local authorities powers to institute a system of periodic measurement of the children which would afford definite information on their physical condition and development. He emphasised the fact that what he proposed was of an optional character. He did not want to detain the House by enlarging on the great value of the information that would be supplied by an anthropometric measurement of school children. Its value had been pointed out at the Hygiene Congress and at the British Association. It would give them information to know whether physical deterioration was going on, and in this connexion he would draw the attention of the House to the valuable report on the condition of school children in Glasgow which had been made by Dr. Mackenzie and Captain Foster. The results which they had arrived at were of very great importance. They were almost startling, for they showed conclusively that the weight and height and physical condition of children depended absolutely on the conditions of the homes in which they were brought up.

Mr. Butcher seconded the amendment. He said that what they wanted was to get at some scientific basis of knowledge as regarded the laws of health affecting, above all, the population of great towns.

Mr. McKenna thought that the words of the clause covered the objects which the honourable gentleman had in view. They were covered by the words "attending to the health and physical condition of the children." If the amendment were not covered by the words of the clause it would impose a burden on the public funds and was therefore by the rules of the House out of order.

The amendment was negatived without a division.

The Bill was subsequently read a third time.

Tuesday, August 13th.

The Post Office Medical Department.

Mr. Hunt asked the Postmaster-General whether his attention had been called to the report of the Select Committee on Post Office Wages, paragraphs 43 to 47; whether the officer of the post office thus mentioned had since giving his evidence before the select committee been given a considerable increase to his salary; whether he would state the reasons leading to the additional emoluments being paid to this official after tendering such evidence; and, in view of the report, what steps were to be taken to insure efficient service in the post office medical department.—Mr. Sydney Buxton (by written answer) replied: I have read the paragraphs referred to. As the honourable Member was informed, in reply to a question asked in this House on April 29th last, the increase in the salary of the chief medical officer was authorised, before he gave evidence before the committee, on the ground that the salary was not considered to afford adequate remuneration for the duties of the post. The recommendations of the select committee will receive the most careful consideration.

Lunatics in London Workhouses.

Mr. Cooper asked the President of the Local Government Board whether he could state the number of men and women, giving the number of each sex, who were detained in the London workhouses as harmless lunatics on account of senile decay or imbecility; if he could state whether any children and, if any, how many, were detained in the London workhouses because of imbecility or idiocy; whether he was aware that no child under five years of age could be admitted into one of the imbecile asylums of the Metropolitan Asylums Board; and whether he would consider the desirability of altering this regulation.—Mr. John Burns furnished the following written reply: The number of the insane in the London workhouses on January 1st last was 322, of whom 159 were men, 149 women, and 14 children. The nature of the lunacy from which these persons were suffering is not specified in the returns. The rule that children under five years of age should not be admitted into the institutions of the Metropolitan Asylums Board for imbecile children was made because it was felt that a trustworthy judgment cannot be formed as to the intellectual condition of very young children. The Local Government Board have, however, intimated to the managers that they would favour arrangements for the reception of children of the kind in question in such a way that they might be carefully observed by an expert before being finally drafted into an asylum.

The Plague Statistics.

Mr. Rees asked the Secretary of State for India whether the deaths from plague in June last amounted to more than 0·2349 per mille; and whether the like figure for the six months ended June amounted to more than 3·8 per mille of the population of India; what were the losses from cholera and fever and other chief epidemics for the same period; whether the like figures were available in respect of other parts of Asia of more or less similar climatic conditions; and, if so, whether he would lay them before the House.—Mr. Morley replied: The honourable Member has correctly stated the mortality from plague in India as a whole during June last and the six months ending June respectively. I am unable to give the corresponding figures for other epidemic diseases, as the mortality from them is not reported month by month to me. In 1905, the latest year for which complete figures for British India are available, the mortality rates for cholera, small-pox, and fevers were 1·97, 0·32, and 19·74 per mille respectively. I have no information that would enable me to reply to the last part of the question.

Wednesday, August 14th.

The Administration of the Vaccination Bill.

Sir William Collins asked the President of the Local Government Board whether, in the event of the Vaccination Bill, 1907, passing into law, he would at once direct that revised notices to be given by registrars of births to persons registering the births of children containing the form of statutory declaration set out in the Schedule to the Bill, should be supplied to registrars of births in the month of September so as to enable persons desirous of taking advantage of the Act in January, 1903, to be provided with the necessary forms in respect of children born within four months of the passing of the Act.—Mr. John Burns (by written answer): I am aware that a new form of notice by registrars to persons registering the birth of children will be necessary in the event of the passing of the Bill. I am considering how far it may be practicable to meet the point suggested by my honourable friend.

children were over-stimulated. It was a slur to our civilisation that there should be so many homes unfit for children to live in. But there were also many schools utterly unsuitable and much money would have to be expended in rebuilding them.

Miss ADLER, speaking as a school manager, said no one could see the homes she had seen and wish children to remain in them. There were but two or three rooms. There was no space for spontaneous development. The mother had to scrub, to mend, and to cook, and the children went out into the streets, where they acquired bad language, vices, and vagabond habits that made them dislike school, and which it was most difficult to correct. If, however, they went to school before the school age they acquired a liking for school and were easily trained.

Mr. PERCIVAL SHARPE thought both sides in the discussion were right; the difference was due to the starting point. The old-fashioned infant schools with the "baby galleries" were an abomination, but children would be better at a model school than at home. Economic conditions were changing; we could not consider the extra expense but only the extra advantages.

Dr. CUNTZ expressed his great surprise at the whole discussion. In Germany the law was emphatic. No child could be admitted at school before the age of six years, and if at all delicate he might remain at home till the age of seven. But then there were no such awful homes in Germany as had just been described by the previous speakers. Widow mothers and others in poor circumstances were widely supported; there was no such degrading distress as seemed to prevail in England.

Mr. H. B. BRACKENBURY (Hornsey) said that in his district there was no dense mass of poverty and they did not admit children in the school under the age of five years. This helped to postpone measles till that age, which greatly reduced the danger of that disease.

Miss K. PHILLIPS urged that out of the 490 provided schools of London many were conducted on the lines described by Mrs. Kirk, but in Sussex she had seen a school with a gallery for 60 children and only a young girl to watch them for five hours. In bad homes children could sprawl, if it was only in the gutter, and sleep.

Lady O'HAGAN insisted on the great difference between infant and ordinary schools. No general rule was possible. There must be variety. When the "knocker up" came at four or five in the morning the breakfast the mother provided at that hour was a horrid affair, and when she came home she was often too tired to give more than bread-and-butter for dinner. Certainly the children of such a home were better off in a well-appointed infant school.

Dr. CRONIN (New York) explained that the law had been amended within the last three years and no child under the age of six years was admitted in the schools. He had then to prove his age, and this law had helped to secure a more punctual registration of births. If this congress would decide that infant schools were a necessity he felt sure New York would not hesitate to give the children "the proper kind of mud." As they had got to grow they might as well grow scientifically instead of allowing children three years old to rule their mothers.

Mr. ABEL (Nottingham) thought that children should remain at home till the school age; but the higher they rose in the animal scale the less instinct ruled and the more was the organised State called upon to fulfil the part of the mother.

Dr. NEWSHOLME now replied, pointing out the inconsistencies of his critics. Thus they had been told that infant schools were to be recommended as good sleeping places; others said that the infants learnt no bad language. In that case they should remain there all day. Others said that it was the best way to discover early disease, or to avoid being run over, or to teach children how to play. But they all knew how to play and only needed the opportunity. The question was whether the actual school was better than home and not the ideal school sketched by Dr. Hogarth. Ventilation had not been improved. The real point was whether they were to encourage the employment of women. He thought not. They should mind the children.

The Closure of Schools or the Exclusion of Patients.

The members of Section II. had attended the above debate as well as the members of Section VII. and there were times when the vast theatre only afforded standing room, but the moment the discussion closed there was a rush for the doors. Other papers were read subsequently, but there was not such a good attendance. Among the various authors may be mentioned Dr. WILLIAM BUTLER (Willesden) who spoke on the influence of school attendance on the spread of non-notifiable diseases, and Dr. J. R. KAYE (Wakefield) who communicated a paper entitled "Closure v. Exclusion in Relation to School Diseases." The experience the speaker had acquired as medical officer of the West Riding of the Yorkshire county council led him to the conclusion that in the case of infectious diseases individual children or perhaps a whole class should be excluded. This generally sufficed and there was no need to interfere with the progress of education by closing the entire school. But in actual practice it was financially more advantageous to close the entire school than to exclude a few pupils. If some pupils were excluded this lowered the average attendance at the school and the grant to the school was reduced in proportion. If, on the other hand, the school was completely closed then due allowance was made and there was no loss. Dr. Kaye thought that a means should be devised to prevent a loss resulting from the taking of proper precautions.

On the Thursday morning Dr. C. J. THOMAS, assistant medical officer of the London County Council Educational Department, presented a paper well charged with statistics on measles. At Woolwich systematic investigations had been made in respect to 5512 children and it was found that of the children entering the infant schools at the age of three years no less than 54 per cent. had already suffered from measles. When they left at the age of six years, then 84 per cent. had contracted this disease. After the first case there was generally quite a number of cases some nine to 11 days later. Woolwich also was divided in half; on one side the policy of school closure was carried out rigorously, while in the other half only the patients were excluded. This experiment demonstrated that the most drastic school closure made no difference whatsoever in the number of cases. The only means of hindering the spread of measles was the building of more sanitary, better ventilated, and larger schools, and the employment for the sick of properly trained nurses who would know how to minimise the danger of infection. A very lengthy discussion followed this paper and Dr. SIDNEY DAVIES, medical officer of health of Woolwich, in a carefully prepared paper, fully confirmed the above views.

Tuberculosis and Schools.

In this section Dr. W. OLDRIGHT, professor of hygiene at the University of Toronto, read a paper on the Schoolroom as a Factor in the Production of Tuberculosis. According to the Ontario statistics women teachers were especially susceptible and the same was noted in the United States. The fact was that in rooms where there were many persons together each person required 3000 cubic feet of air; and as in practice the air could not be changed more often than about three times in an hour every person should have 1000 cubic feet of space. Nothing of the sort existed and there was not only a lack of air but chalk dust and all kinds of irritating particles were present in the vitiated air. In some cases the mortality among women teachers from tuberculosis was as high as in the most dangerous trades, such as those of printers and stone-cutters.

Dr. LOUIS GOURICHON, formerly President of the Society of Medical School Inspectors of Paris, presented a paper written in quite a different strain, in which he stated that tuberculosis was relatively a rare occurrence among the male and female teachers of the Paris elementary schools, and when there was a case it was generally contracted outside the school. This disease could not be considered as a professional malady so far as teachers were considered.

But, again, and in contradiction to the above, Dr. C. C. JESSEN, physician to the public schools and president of the Society of Physicians of Copenhagen, presented a paper in which he said that the mortality from tuberculosis among the Danish teachers who were insured was twice as high as among the insured of the general population. He therefore urged that no teacher should be appointed unless he could present a medical certificate to show that he was free from tubercle of the lungs and larynx. On the other hand, all teachers dismissed for tuberculous disease should receive a pension equal to at least two-thirds of their salary.

Ringworm in Schools.

There were also many papers on skin diseases and ringworm. Dr. P. S. ABRAHAM thought the present methods of prevention in the metropolitan elementary schools absolutely

Notes, Short Comments, and Answers to Correspondents.

A POINT IN POOR-LAW PROCEDURE.

WE have received some newspaper cuttings which refer to a rather curious point which has recently arisen before the Watford board of guardians. It appears that a patient in the Watford Infirmary was operated upon by Dr. James Buchanan, the district medical officer of Watford who had occasion to ask a brother practitioner to administer an anæsthetic. Dr. Buchanan accordingly applied to the board for payment of one guinea to the medical man in question, when the board riposted by asking Dr. Buchanan why he had operated upon the patient instead of obeying the instructions of the board to transfer the case to the Watford District Hospital. Some of the guardians proceeded to take a very high hand with Dr. Buchanan. One lady objected to the payment of the fee which would have been avoided if the patient had gone to the district hospital. Another called attention to the medical man's disobedience to orders; and a gentleman with a military title laid stress upon the fact that the medical man was the servant of the board. At the next meeting of the board, however, one of the guardians read a letter from the treasurer of the Watford District Hospital saying, "Pauper patients are not admitted to the hospital. The infirmary is the proper place for pauper patients," a document which showed that the alleged disobedience of the medical man was really an appreciation of the proper course to be pursued. We think that the action of the board shows an amount of distrust of their medical officer which is a little remarkable. Of course, the proper person to perform ordinary operations upon patients in the Poor-law infirmary is the medical officer of the infirmary, and the proper place for their performance is the infirmary; and the fee for the administration of an anæsthetic ought not to be grudged to the unfortunate patient; and the board ought not to attempt to sponge upon the district hospital.

A MEDICAL OFFICER OF HEALTH AND A PRESCRIBING DRUGGIST.

AN unusual scene recently occurred at a meeting of the Stowmarket urban district council, in which the protagonists were the medical officer of health of the district, Dr. C. W. Low, and the chairman of the council, Mr. Gostling, a druggist of the town. Dr. Low reported to the council that a local druggist, whom he did not name, had failed to notify a case which he (the druggist) had recognised as erysipelas and prescribed for as such. Dr. Low submitted that this was an infringement of the Act which requires that in default of the nearest relative, every person in charge of, or in attendance upon, the patient suffering from a notifiable infectious disease shall send notice of a case to the medical officer of health. An animated discussion ensued between the chairman and Dr. Low, the former objecting to the use of the term "druggist" to denote a pharmaceutical chemist and insisting that Dr. Low had used the word contemptuously, which the latter denied. The chairman then asked whether Dr. Low thought a druggist was capable of diagnosing erysipelas and received the very proper answer that whether he had correctly diagnosed it or not, if a druggist believed a case to be erysipelas and treated it as such he was bound to notify it to the medical officer of health. The debate waxed somewhat acrimonious and it shortly became apparent that it concerned the chairman intimately, for at his urgent instance Dr. Low reluctantly informed the council that the chairman himself was the offending druggist. There was a good deal more discussion which led to nothing except a suggestion from a councillor that Dr. Low had acted rightly in reporting the matter. It is obvious that he did no more than his duty and that Mr. Gostling had failed to comply with the provisions of the Act.

A NEW RAILWAY SALOON FOR INVALIDS.

THE London and North-Western Railway Company has forwarded to us a description of a new type of saloon that it has recently constructed for the accommodation of invalids which seems to mark a considerable advance on anything of the sort that has been produced hitherto. The saloon contains a central compartment, which is 18 feet long, for the invalid, entered by folding-doors which admit of the introduction of a bath-chair. This portion contains a fully furnished brass bedstead and a couch and lounge chairs of a comfortable aspect. The apartment has been elaborately upholstered and has been planned with a view to avoid vibration as much as possible. A lavatory adjoins the saloon and at each end of the coach are a first-class compartment with lounge chairs that can be converted into beds and a lavatory adjoining each. Every possible comfort and convenience for an invalid and his companions who desire to make a long journey seem to have been provided. Medical men having feeble or bedridden patients whom they wish to send away from home on this company's system may be glad to know of this service, which will probably be followed by the other large railway companies.

HOSPITAL PARASITES.

THE *World* in its issue for August 13th contains a most useful article for public consumption which is headed "Parasites: A Study of Lay Ethics." The article contains a singularly straightforward statement of the main facts of the abuse of hospital out-patient departments by non-indigent persons. The writer points out the triple fraud that is daily perpetrated upon the deserving poor, the charitable public, and the medical profession, and remarks:—"For the comparatively well-to-do to abuse hospital charity is therefore, perhaps, the meanest type of fraud the resources of latter-day civilisation have yet evolved." He proceeds to express his conviction, from personal investigations, that it is not the wealthy who personally defraud hospital charity. "The legendary duchess, who, borrowing her maid's gown, attends the out-patient department in order to economise her fee for medical advice, is apocryphal. ..... The parasites on hospital charity prey vicariously. They send their servants and dependants." The writer fairly claims that a domestic servant, earning a good wage, besides her board and lodging, is not a fit subject for free medical relief, even if her employer is unwilling to assist her in obtaining medical advice. He very rightly lays stress on the evil tendency that the hospital letter system has in promoting this form of abuse. In acquitting the wealthy classes of defrauding the hospitals in person, he qualifies his verdict as follows: "If they are on economy bent a much more comfortable plan (and one very generally practised) is to call in a medical man and then not to pay the fee until a convenient season or even until active unpleasantness threatens. At whatever inconvenience to himself, the doctor can always wait." He proceeds, however, to record an amusing instance of how a surgeon did not wait, much to the discomfiture of a wealthy parasite. We are pleased to read in a widely read newspaper so able a statement of the dishonest actions to which many otherwise respectable persons will stoop in their dealings with medical men, and we trust that the message may reach at least a few of these offenders.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—I should be glad if you could tell me of a sanatorium where a young artisan suffering from pulmonary tuberculosis and asthma could be treated for a few weeks; he can only pay about £5. His condition is steadily improving. If unable to give the information, would you ask your readers if they could do so.

I am, Sirs, yours faithfully,
P. S. L.

August 13th.

⁂ As a rule, patients suffering from asthma with pulmonary tuberculosis do not do well under sanatorium treatment. We do not know of any sanatorium to which the patient could be sent for much more than a week on a payment of £5. As he is improving had he not better stay where he is?—ED. L.

◆

Etiquette.—We do not think that our correspondent should advertise his change of address in the newspaper, at any rate he must only do so with discretion. He should send notices round to his patients.

Suffolk.—We do not think that any such institution exists either in France or in Italy.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (3 P.M.), St. Mark's (2.30 P.M.).

TUESDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. journals belonging to the association should only quote the German articles that appeared in the journals of the German Association of the Medical Press, for they at least did exercise a veritable control. This was the beginning of a really serious action, and if it continued successfully the International Association of the Medical Press would soon become a great power for good.

A lengthy conversation followed as to what could be done that would not be illegal. A black list in Belgium would probably be considered illegal and in all countries it is difficult to point out that a person is not pursuing an honourable course without incurring the risk of an action for libel. Also, as the French delegates pointed out, there was no unanimity as to what was honourable or not. There were men working for months and years at scientific research for which they received no pay whatsoever. Might they not occasionally endeavour to make ends meet by undertaking scientific experiments for some manufacturers? It might be said they were special pleaders and made the best of the case. If that was so, what was the difference between them and a barrister who pleaded to the best of his ability for a prisoner whom he nevertheless believed to be guilty? All these were very difficult, delicate matters on which it was not possible to dogmatise. But the Germans had succeeded in putting their hands on something tangible. For medical men to go round from manufacturer to manufacturer offering to so "cook" the record of their cases that it would serve to advertise some drug was obviously infamous, and this not merely in the professional sense of the term. Such flagrant cases must be stopped and stopped internationally. There was some difficulty in framing a proposition to express this determination, but, finally, the committee agreed on the following text, which was unanimously adopted:—

> The International Association of the Medical Press, taking into consideration the articles written by medical men in favour of medicinal products, urges the national associations to exchange with one another information on the character of these articles and of their authors.

The next question discussed related to the necessity of refusing to publish certain sorts of advertisements. But if one paper, actuated by high conscientious motives, refused to publish an advertisement the good object held in view would not be attained if the other papers did not also refuse to insert the advertisement. Here, as in almost all these questions, it was necessary to act in concert. Fortunately, in Germany some 50 periodical publications had been brought into line and it sufficed for one of these papers to refuse an advertisement and all the others would also refuse the advertisement. But now the Germans were anxious to extend this action beyond the frontiers. They desired to know what were the sort of advertisements that were condemned in England or France and they would see that none of them appeared in German papers. On the other hand, they asked the English and French papers not to open their advertisement columns to what in Germany they considered to be unworthy of their profession and of science. As a result of this discussion the following motion was adopted:—

> The International Association of the Medical Press urges all the National Associations of the Medical Press to come to an agreement in regard to the medical advertisements that should be refused.

This terminated the discussion and the resolutions arising out of the German report.

In regard to the French report Dr. DOLÉRIS said that nothing short of a complete revolution would mend matters in France. Fortunately, they have now something to go upon; they could quote the German example. But he inquired how the Germans managed to keep dishonourable members out of their association.

Professor POSNER explained that in Germany there was an executive committee of five which decides, but it was always a difficult and delicate matter to reject a member. He thought that no new member or journal should be admitted without a proposer and seconder who would be prepared to answer all questions put.

Dr. DOLÉRIS said that something of the sort used to be done in France, but now there was a great deal of canvassing and there would be a large meeting and a large vote, but a big society or assembly could not possibly and discreetly investigate very delicate matters touching the honour of the candidate.

The French delegation did not present any resolution. As for the British delegates, they only intervened in the discussion to explain how matters stood in England and in several instances were able to state that some portion of what was desired had already been realised in this country.

In the evening the committee, together with some friends, were entertained to dinner by Mr. and Mrs. W. Arbuthnot Lane at their residence in Cavendish-square. When the time for the toasts was reached Mr. ADOLPHE SMITH was again the spokesman for the British contingent and he expressed his confident belief that all who had helped the present meeting had helped a great cause. Their host, Mr. Arbuthnot Lane, had decorated his table with three colours. The flowers on the table were all red; this was the colour of life and energy. But they hung in garlands over green moss and green was the colour of hope. All else was white and white was the colour of purity. In thus meeting together they hoped to acquire the energy to purify the press. French, German, and Belgian delegates followed with well-chosen words expressing their gratitude to their English hosts for their hospitality and for the true friendship and kindness with which they had been received.

On the morning of August 4th the committee met again in the Persian hall of Mr. Bland-Sutton's house. The question of congresses was now discussed. Professor POSNER gave assurances in regard to the Fourteenth International Congress of Hygiene and Demography which is to meet in Berlin at the end of September in the building of the German Reichstag. The Bureau of the Press was at the disposal of members of the International Association of the Medical Press, with its 68 seats, electric light, and every convenience. Free press cards would be given granting every privilege, but only to members of the International Association of the Medical Press. Representatives of other journals which were not affiliated would receive ordinary press cards which would only admit them to the meetings and discussions. This was an opportunity of making the medical press throughout the world understand that an international association was in existence and that it was a decided advantage to belong to this organisation. Professor Posner thought the Congress of Hygiene would be a great success, particularly as the more important journals of Berlin had been asked to send representatives to the organising committee.

In regard to the next meeting of the committee of the International Association of the Medical Press, Professor POSNER invited the committee to meet next year at Berlin when convenient, but probably shortly after Whitsuntide and when the holiday rush was over. They would then have to prepare for the Budapest Congress and for the general assembly of the International Association of the Medical Press, which must be held immediately before the Sixteenth Medical Congress in 1909.

A long discussion now ensued as to whether, as the medical press was now a permanent international organisation, it could do anything to modify the present chaotic condition of affairs in regard to international scientific and more especially medical congresses. Undoubtedly a permanent international bureau should be created to regulate and to prevent the clashing of congresses and to limit their number. The Medical Congress came to an end each time. The president and secretaries of the next congress had to begin all over again. They could not, and did not, profit by experience acquired at previous congresses and the repetition of blunders was only varied by the idiosyncrasies of the different countries where they met. At Lisbon the Portuguese seemed to resent outside interference and it was feared that if there was a permanent international secretary he would acquire too much power. They might, however, have an elected international committee that would negotiate with the secretary of the next congress. Some organisation must be formed. At present everyone who chose started a congress just when and where it might suit his fancy. There must be a central bureau to prevent the confusion this caused. Small countries were special transgressors in this respect, for they knew but little of the history of previous congresses.

Sir FELIX SEMON spoke at length on this subject and gave an amusing account of the adventures of the section of Laryngology. Thus in 1891 it was treated as a separate section but as some officer concerned was not popular it was converted into a subsection of medicine so as to prevent personal dispute. At Copenhagen, as there was no local laryngologists of sufficient repute to preside, the section was merged into another section. At Washington, in 1897, the president was deposed because he consulted with a homœopath and the section was merged into another section. At Berlin the section was a great success. At Rome it was united with the otologists, though both parties objected. At Moscow they

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheque and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France.—J. ASTIER 81, Rue Bapts, Asnières, Paris.

in Coventry, 1·5 in Warrington, 1·6 in Bootle, 1·7 in St. Helens, and 2·4 in Smethwick. The deaths from measles, which had been 113 in each of the two preceding weeks, declined to 94 in the week under notice; the highest death-rates from these diseases were 1·1 in St. Helens, 1·9 in Blackburn, 2·2 in Walsall, 2·5 in Cardiff, and 3·0 in Stockton-on-Tees. The fatal cases of whooping-cough, which had been 123 and 66 in the two preceding weeks, were 85 in the week under notice; the death-rates from this disease ranged upwards to 1·1 in Cardiff, 1·2 in Wigan, and 2·3 in St. Helens. The mortality both from scarlet fever and from diphtheria slightly exceeded that recorded in other recent weeks; the former disease caused a death-rate of 1·5 in West Bromwich and the latter of 1·5 in Middlesbrough and 1·7 in Rotherham. "Fever" was not excessively fatal in any of the large towns last week. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital at the end of last week was 3660, against numbers that had increased from 3658 to 3626 in the 13 preceding weeks; 466 new cases were admitted during the week, against 569, 557, and 419 in the three preceding weeks. One case of small-pox was admitted and remained under treatment at the end of the week, being the first case since the middle of May last. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 126, 136, and 137 in the three preceding weeks, further rose last week to 139, and were 17 in excess of the corrected average number in the corresponding week of the five years 1902–06. The causes of 33, or 0 9 per cent., of the deaths in the 76 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Newcastle-on-Tyne, Hull, Nottingham, and 51 other of the 76 towns; the largest proportions of uncertified deaths were registered in Liverpool, Birmingham, Sheffield, Bradford, Sunderland and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 14·9, 13·6, and 12·8 per 1000 in the three preceding weeks, rose again to 13·8 during the week ending August 10th, and was 2·0 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 8·8 in Paisley and 10·6 in Leith, to 15·4 in Dundee and 16·1 in Greenock. The 479 deaths in these towns showed an increase of 34 over the number in the previous week, and included 75 which were referred to the principal epidemic diseases, against 63, 65, and 60 in the three preceding weeks. These 75 deaths were equal to an annual rate of 2·2 per 1000, which exceeded by 1·0 per 1000 the mean rate during the same period from the principal epidemic diseases in the 76 large English towns; they included 30 which resulted from whooping-cough, 22 from diarrhœa, 13 from "fever," six from measles, two from scarlet fever, and two from diphtheria, but not any from small-pox. The fatal cases of whooping-cough, which had been 30 and 12 in the two preceding weeks, rose again last week to 30, of which 15 occurred in Glasgow, six in Edinburgh, four in Dundee, and three in Leith. The deaths from diarrhœa, which had been ten and 21 in the two preceding weeks, further rose to 22 last week, and included ten in Glasgow, seven in Dundee, and two in Leith. The deaths referred to different forms of "fever," which had been 15 in each of the two previous weeks, declined to 13 last week, and included four cases of cerebro-spinal meningitis in Glasgow, two in Edinburgh, two in Leith, one in Greenock, and one in Perth. The six fatal cases of measles corresponded with the number in the preceding week, and included four in Glasgow and two in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 63 and 63 in the two previous weeks, declined again to 55 last week, and were 13 below the number in the corresponding period of last year. The causes of five, or 1·0 per cent., of the deaths registered in the eight towns last week were not certified; in the 76 English towns the proportion of uncertified deaths was 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 21·5, 21·2, and 18·0 per 1000 in the three preceding weeks, further declined to 15·7 per 1000 in the week ending August 10th. During the first six weeks of the current quarter the death-rate in Dublin has averaged 19·3 per 1000, the rate in London during the same period being 11·9 per 1000, and in Edinburgh 12·2. The 118 deaths of Dublin residents registered during the week under notice were 17 fewer than the number in the preceding week, and included 13 which were referred to the principal epidemic diseases, against 12 and 15 in the two preceding weeks; of these, five resulted from measles, five from diarrhœa, and one each from diphtheria, from whooping-cough, and from "fever," but not any from small-pox, or from scarlet fever. These 13 deaths were equal to an annual rate of 1·7 per 1000, the death-rate last week from the principal epidemic diseases being 1·2 in London and 1·4 in Edinburgh. The deaths from measles, which had been three and six in the two preceding weeks, declined again last week to five; while the fatal cases of diarrhœa increased to five last week, having been four and three in the two preceding weeks. The 118 deaths from all causes in Dublin last week included 31 of children under one year of age and 27 of persons aged upwards of 60 years; the latter corresponded with the number in the preceding week, but the deaths of infants showed a marked increase. Three inquest cases and two deaths from violence were registered; and 42, or 35·6 per cent., of the deaths occurred in public institutions. The causes of eight, or 6·8 per cent., of the deaths in Dublin last week were not certified; the percentage of uncertified deaths in London did not exceed 0·2, while in Edinburgh the proportion was 2·2 per cent. The 104 deaths in Belfast included three which were attributed to cerebro-spinal fever.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: E. A. Penfold to the *Hindustan*, on recommissioning; G. Hewlett to the *Prince George*, on recommissioning; E. B. Townsend to the *Terrible*. Staff Surgeon: M. Cameron to the *Hindustan*, on recommissioning. Surgeon: A. J. Hewitt to the *Prince George*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Lieutenant J. R. Forrest has been appointed Sanitary Officer, 3rd (Lahore) Division, as a temporary measure. Lieutenant C. M. Drew has joined at Tidworth. Major C. E. P. Fowler, Captain H. O. B. Browne-Mason, Captain A. L. A. Webb, Captain F. M. Parry, Captain A. D. Jameson, Captain H. B. Fawcus, and Captain H. R. Bateman have joined the London District. Lieutenant-Colonel J. R. Dodd has been appointed to the medical charge of the Royal Infirmary at Dublin.

The undermentioned Lieutenants to be Captains (dated July 30th, 1907): Godfrey F. Rugg, Douglas S. B. Thomson, John Fairbairn, Leonard Bousfield, Robert G. Anderson, James H. Douglas, Robert R. Lewis, Alexander L. Otway, Charles H. Turner, Frank H. Noke, Eugene O. Whitehead, Walter F. H. Vaughan, Richard B. Hole, Travis C. Lucas, George E. Cathcart, William Wiley, Howard Harding, John A. Turnbull, Montagu F. Grant, David P. Johnstone, Edward H. M. Moore, Michael D. Ahern, Frederick J. Garland, Alban A. Meaden, Robert J. Cahill, Sidney C. Bowle, Harry B. Connell, George S. C. Hayes.

The undermentioned to be Lieutenants on probation (dated July 29th, 1907): Thomas McCann Phillips, Harold Stewart Dickson, George Forbes Dawson, Harry Vivian Byatt Byatt, Ronald Ernest Todd, Thomas Fletcher Lumb, Harold Gibson, Charles Paget O'Brien Butler, Gerard Petit, John Berehmans Hanafin, John Allister Renshaw, Richard Frederick O'Toole Dickinson, William Roche O'Farrell, Ralph De Veil King, Dalziel Buchanan McGrigor, Cecil Allen Taylor Conyngham, John Ross Lloyd, William Charles Carson, Richard George Stanhope Gregg, Harold Thomsett Treves, Francis Thomas Dowling, James Clarence Ledeatt Hingston, Forbes Jackson Stuart, Benjamin Alexander Odlum, William Arthur Spong, James Forgan Grant, Henry Percival Hart, Arthur Edward Booth Jones, and Alexander Hendry.

Lieutenants Ronald E. Todd and James C. L. Hingston are seconded under the provisions of Article 349, Royal Warrant for Pay and Promotion, 1903 (dated, July 29th, 1907).

vaccine, obtained trustworthy evidence of clinical improvement within an hour after inoculation. The augmentation of the opsonic power and the clinical improvement which are here in question were, as you will appreciate, correlated, in the case where very small doses of vaccine were employed, with the development of the ordinary positive phase, and, in the case where moderate doses of vaccine were employed, with the development of that feature in the curve which was referred to above under the designation of the initial rise.

Question as to whether it would not be possible by Piling one Inoculation upon another to Achieve a Larger Output of Antibacterial Substances and in Association with this a Positive Phase of Longer Duration.

It will be every man's—at any rate, every beginner's—thought that it ought to be practicable to achieve a larger output of antibacterial substances, if not by the employment of larger doses of vaccine, then assuredly by piling up inoculation upon inoculation. I have already discussed this question elsewhere,[2] and have pointed out that, while it may be possible in connexion with certain vaccines and the employment of submaximal doses—using the term submaximal doses here to denote doses smaller than those which would give maximal immunising response—to obtain cumulation in the direction of the positive phase, such a result can with other vaccines—and in particular with tubercle vaccines—very rarely, if ever, be obtained. Where this situation confronts us the proper policy would appear to be to treat each inoculation as an independent event, following up one inoculation by another as soon as the effect of the antecedent one is passing off.

Question as to whether it is Expedient to Employ in Successive Inoculations Progressively Increasing Doses of Vaccine.

Close kin to those primitive ideas which suggest that the immunising response *must* increase proportionately with the dose of vaccine employed, and that failing this it *must* be possible to obtain an increased immunising response by piling one inoculation upon the other, is the idea that it *must* be possible to achieve a greater yield of protective substances by employing in successive inoculations doses of vaccine increasing by geometrical progression. In point of fact, experiment shows clearly, not alone that no advantage is reaped from such progressive augmentation of the doses of vaccine, but that such a system of dosage must inevitably culminate in disaster. Indeed it is obvious, on *a priori* considerations alone, that where the dose of vaccine is progressively augmented a point must sooner or later be arrived at when the immunising power of response will give out. I would therefore put it to you that the proper principle of dosage in connexion with any series of inoculations is never to advance to a larger dose until it has been ascertained that the dose which is being employed is too small to evoke an adequate immunising response. I regulate in practice the dosage of bacterial vaccines for therapeutic purposes in accordance with the following scheme. Where an examination of the patient's blood taken 24 hours before inoculation shows a subnormal index, and examination of his blood taken 24 hours after inoculation shows that the index has been considerably reduced, I take it that the smaller dose would have been appropriate. Where examination of the blood 24 hours after inoculation shows that the index has been raised, and where after the expiration of an interval of a week or ten days the index has fallen back to what it was before inoculation—the patient having experienced throughout nothing in the form of constitutional disturbance—I take it that a larger dose might appropriately have been administered. Where in association with a slight initial fall after inoculation the index is, after the expiration of a week or ten days, found to stand higher than it was at the outset, I take it that an appropriate dose has been administered.

Question as to the Site which Ought to be Selected for the Inoculation of a Bacterial Vaccine.

A whole array of observations point to the local production of bacteriotropic and vaccinotropic substances generally at the site of inoculation. We have, in the first place, the observation that an infinitely greater yield of antitoxins—and it would seem also of antibacterial substances generally—is achieved in horses by the subcutaneous as contrasted with the intravascular method of inoculation. We have, further, the observation, in connexion with antityphoid inoculation, that seemingly a *more effective* protective reaction is induced in patients who show considerable local reaction at the seat of inoculation than in those who suffer from severe constitutional symptoms apart from any appreciable local reaction. We have further observations to the effect that local immunity may be acquired and retained apart from the requirement or retention of general immunity. If we may build—as it would seem that we may—upon the aggregate of these observations, it would logically follow that the site of every inoculation which is undertaken for therapeutic purposes deserves to be very carefully considered in connexion with the site of the focus of infection which is to be influenced. We may speculate as follows. Where protective substances pass into the blood through a channel which does not lead through the focus of infection—let us, for the purpose of fixing our ideas, suppose that focus to be situated in a lymphatic gland—the newly elaborated protective substances will come into operation upon that focus only after they have been diluted by the whole volume of the blood. Where, on the contrary—if I may so express it—the inoculation has been made "up stream" from the focus of infection—i e, in some part of the lymph watershed which drains through the focus of infection—the protective substances which are produced at the site of inoculation may be expected to come into application upon the focus of infection in a comparatively undiluted condition.

Pending the time when the place of origin of the bacteriotropic substances which appear in the blood after inoculation shall have been definitely set at rest by some *experimentum crucis*,[3] I have made some tentative therapeutic experiments on the relative efficiency of inoculations undertaken up stream from the focus of infection as compared with inoculations made in regions which were not so related to that focus. I feel satisfied that those experiments—though they at the same time indicate that one and the same portion of tissue tires out on too frequent inoculation—have furnished results conformable to those which might have been expected to follow from the theory of the production of bacteriotropic substances at the site of inoculation. To take only one case out of many, I was much impressed by the fact that the theory of the local production of protective substances suggested a procedure which successfully arrested, after all other methods had failed, the spread of a tuberculous process which long defied treatment by the ordinary method of inoculation. This successful result was obtained in the case of an ulcer which, though it had completely healed in the middle, was spreading outwards in the form of a ring of indurated tissue. Its arrest and definite cure were achieved when—executing a strategic move—I inoculated the tubercle vaccine in a number of different points disposed circle wise around the extending ring.

An Acquaintance with the Physiology of the Immunising Response is not a Sufficient Equipment for an Immunisator.

Up to this point we have been dealing with the physiology of immunisation and the nature of the immunising response. For the successful treatment of bacterial disease by methods of immunisation something more is required. We must realise the conditions under which bacteria cultivate themselves in the organism. We must understand in what circumstances bacterial products or, as the case may be, bacteria are conveyed into the blood stream from local foci of infection. We must appreciate how the organism reacts to such '*auto-inoculations*.' And we must understand how to bring the leucocytes and bacteriotropic substances which are the instruments of immunisation into operation upon bacteria which are cultivating themselves inside the organism but outside the blood stream.

Conditions which Obtain in the Foci of Bacterial Infection.

We may conveniently begin with the study of the conditions which obtain in foci of bacterial infection. I have already often pointed out that the foci in which bacteria accepted as causal factors in the spread of the disease: contagion from person to person, contaminated food-supply, wearing apparel, &c., rats, fleas, and other animals. That rats have always played a very important part in the spread of plague is no new theory. A Puranâ written over 800 years ago in India runs as follows: "When you notice an unusual mortality amongst rats it is a sure sign that you are shortly to be visited by a fatal disease, and your only safety lies in flight." Early in the present epidemic the natives learned to associate the connexion between rats and plague. In 1905 I carried out a series of experiments to prove the connexion between rats and fleas in the spread of plague. I had done one or two experiments in 1901 but had not the time or opportunity then to go fully into the matter. In 1900 and 1901 from observations and experiments it seemed very clear that rats and fleas were two leading factors in the local spread of the disease. Food-supply, especially grain, has always in my mind been accountable for the spread of the disease, but chiefly amongst rats. Experiments carried out in 1902 and afterwards in 1904 and 1905 corroborated the previous conclusions. On the above supposition I have always divided plague into the classes bubonic, pneumonic, and alimentary. In an article published in THE LANCET of June 10th, 1905, p. 1562, I gave this latter division and my reasons for thinking so. In the first years of the present epidemic all foodstuff that was found in infected go-downs was either destroyed or exposed to the sun for several days. This was only a measure, however, carried out in one or two places and in my opinion should be much more enforced.

---

[2] Clinical Journal, May 16th, 1906; Transactions of the Royal Medical and Chirurgical Society, vol. lxxxix.

[3] I would throw out in this connexion the suggestion that the production of protective substances at the site of inoculation would be definitely set at rest if after the inoculation of a bacterial vaccine into a limb it were shown that an increase of protective substances in the blood could be achieved by either massage and the application of a Bier's bandage.

There can be nothing but praise for the strenuous efforts made by the various Governments in India to stamp out the disease and prevent its spread, but it has always seemed that too much weight is given to certain lines of action even after the results were there to prove their faultiness. Then, again, too much importance is given to various methods of inspection and segregation employed in certain places where plague has not made headway. To say, for instance, that railway inspection and notification have kept Madras city free from plague is asking one to accept too much for these precautions. It is one of the puzzles connected with this disease that have still to be answered. Black Town, in Madras city, in about as favourable a locality for the disease to thrive in as one could seek for. Plague cases have occurred there, but the disease has never made headway. Why? Take Calcutta. Plague should have swept the city but it has not. There are still several questions which require answering before we can get to the bottom of the periodical recrudescence and disappearance of this disease. And because Madras and Calcutta are free to-day it by no means follows that they will remain so for ever. Several districts lived under that false impression for one or two years, only to feel the scourge more acutely when it did come. There is one important district in Mysore State in which plague, at least during the past two years, has been a more or less minus quantity. That is on the Kolar Gold Fields. Plague used to visit the fields regularly almost every year. The dislocation to the work can be well imagined. The part of the fields where the coolies live is about nine miles long by about one wide. The coolies live in tattie huts erected in long parallel rows. Each hut stands by itself. If a case of plague occurred in one of these huts it was pulled down and burned. The inhabitants were segregated and the adjoining huts were also evacuated. These precautions no doubt curtailed the disease to a certain extent but the disease ran its course. In 1904 it was decided to commence at the north end of each camp and go right through, digging up the floor of each hut and destroying all the rats. When this was done the performance began all over again. This was carried on through 1905 and 1906; in addition in the latter year "Liverpool rat virus" was laid down all over the fields, commencing at one end and going clean through. It so happened that in the extreme north end was a closed down mine and the virus was not laid down in that quarter. Within a fortnight of the experiment word was brought to the "Lab." that many rats were making their way to the north end of the field and one or two were found dying in outhouses. From these dying rats I was able to isolate a bacillus identical in every way with the original Liverpool rat virus bacillus. The outbreaks of plague on the fields have become less and less. Isolated cases have occurred, but the disease has never spread to any extent since these two plans have been carried out. Yet in the neighbouring villages, which abut on the fields, plague is constantly occurring. In towns and villages it would be impossible to carry out the former of these two methods to any extent, but the use of the "Liverpool rat virus" might be extensively used in conjunction with other exterminators. The results on the gold fields appear so satisfactory that they are worthy a more extended trial.

Haffkine's prophylactic should be pushed more than it is. Unfortunately, it has not found favour with the whole of the medical profession in India and in Madras Presidency it has not been used very much for that reason. It is also supposed only to confer immunity for at most six months or so. This belief has told against its use in many places. There is, further, a widespread impression amongst the natives that it produces impotence. Now, if we have a considerable portion of the public in Great Britain objecting to vaccination and allowed by Government to carry out their objection to the point of refusal, thereby building up an ever-increasing population of unprotected individuals until one day we have a general and widespread outbreak of small-pox, how can we afford to laugh at the uneducated Indian because he will not come forward for inoculation? The problem is not an easy one, but it is one that must be tackled. This yearly death roll is becoming a very serious matter. Plague has long ago ruined the trade of Bangalore; Poona has suffered and is still suffering; the Punjab is in a pitiful condition; at any moment the disease may break its present bounds and flow over the Straits Settlements and Ceylon and the consequences are not difficult to conceive.

The treatment of plague has not made much advance during the past years. Various sera have been tried with disappointing effects. Carbolic acid injections have done good in many cases and at one time it was thought that it would prove very efficacious. Adrenalin has been boomed, but cardiac stimulants are still the chief mainstay. There is one drug which so far I have not seen mentioned and which I used in 1906 on four or five cases with remarkable results. This is collargol, an allotropic form of silver. It is soluble in water about 1 in 25. I used it in intravenous injections, one cubic centimetre of a 1 per cent. solution. The first case was hardly a fair test, but the result was astonishing.

A man was admitted into the plague hospital about 8 A.M. He had double cervical buboes. His temperature was 104·6° F. and his pulse was 130. He was highly delirious and death seemed imminent. So hopeless was his condition that at first I refused to try the drug. However, I gave one cubic centimetre of a 1 per cent. solution intravenously; this was at 9.30 A.M. I called down again at 5 P.M. The temperature was 100° and the pulse was 105. The wild delirium was gone but he was picking at his blanket. It was evident that the bronchial glands were infected, also the apices of his lungs. I repeated the injection. Next morning his temperature was normal, his pulse was 105, and he was able to answer questions. I did not repeat the injection. His breathing was very laboured and the upper portion of his lungs was quite dull. He died on the following day. The necropsy showed infiltration of all the cervical glands, bronchial glands, and consolidation of the upper and middle lobe of the right lung and upper lobe of the left. I felt satisfied that the drug had had a beneficial effect on this man's case. Had he not received it I am sure that he would have died the same day.

The next two cases were men with inguinal buboes. They had been ill 24 hours previous to admission. They had temperatures over 101°; the buboes were exquisitely painful. I gave both intravenous injections of one cubic centimetre of a 1 per cent. solution in the morning; by evening their temperature was normal. The injection was repeated next morning. The temperature never rose again and the buboes disappeared in three days, both men being up and about on the eighth day. The other two cases were in children. I was unable to do intravenous injection and after two days' illness both died. The drug, I think, merits further trial. I was not in charge of the plague camp and it was only by the courtesy of the native doctor that I was allowed to carry out this treatment.

I am, Sirs, yours faithfully,

ALEX. M. ELLIOT, M.B. Edin.

Cliveden-place, S.W., August 12th, 1907.

THE GEOGRAPHICAL DISTRIBUTION OF HERNIA.

To the Editors of THE LANCET.

SIRS,—Though I was well aware that abdominal hernia is a complaint common to all nationalities I was not sure whether the varieties we are familiar with in this country

Where we elect to employ the method of evacuation as distinguished from the method of dispersion our choice will lie between simple incision, incision followed by dry cupping—as advocated by Klapp—and evacuation by aspiration. This last method has, I submit, an advantage over all others in the respect that it does away with all scarring and minimises both the risk of the entrance of bacteria from without and the risk of auto-infection of the edges of the wound. It also secures more effectively than any method of incision and drainage what is in the case of an abscess the obvious desideratum, to wit, the filling up of the evacuated cavity with an antitryptic and opsonic lymph which will both inhibit bacterial growth and arrest further digestive destruction of the tissues.

(c) *Removal of obstacles to the free streaming of lymph through a focus of infection.*—We have seen above that a deficient outflow of lymph and the formation of a lining of fibrin on its walls are in the case of a sinus favourable to the survival of the infecting microbes. I am accustomed to combat these conditions by introducing into every dry sinus a solution of 0·5 per cent. citrate of soda and 5 per cent. sodium chloride.[5] It will be understood that the citrate of soda prevents coagulation and scabbing by decalcifying the lymph, and that the salt, acting by osmosis, causes fluid to transude from the blood-vessels. Under the influence of this application a clear lymph wells out from every choked sinus, and the local conditions rapidly improve. The situation in the case where we have a carbuncle or brawny swelling of the subcutaneous tissues being, in the respect that the lymph stream is obstructed, essentially similar to those which have just been considered, it must be treated on the same principle. I may perhaps in this connexion make brief reference to a case of Ludwig's angina which came not long ago under my observation. The patient, a middle-aged man, had in the first instance developed what was taken for an indolent furuncle in the parotid region. When, after considerable delay, this was incised no trace of pus was met with, and the tissues were found to be everywhere dry and infiltrated. They remained in this condition and the wound showed absolutely no disposition to heal. Two weeks later the patient, who up to that time had been taking out-door exercise, was suddenly taken seriously ill, and the brawny swelling, which up to that time had been limited to a patch on the left cheek, spread rapidly round under the jaw from one ear to another. A surgeon now carried a series of vertical incisions deep down into the indurated tissues. Twenty-four hours afterwards the patient had lapsed into a condition of low delirium, and the local conditions showed no sign of improvement. When brought to see him I could not, even at the bottom of the gaping incisions, find sufficient moisture to fill the loop of a platinum needle. Film preparations obtained by pressing cover-glasses against the sides of the wound showed very abundant streptococci, and only here and there a leucocyte. Blood drawn from a vein at the elbow with the intention of making a culture clotted instantaneously in the syringe. It was immediately clear that what was most urgently required in this case was, not that further means of antibacterial defence should be furnished to the patient but that such means of antibacterial defence as were already at his disposal should be brought into application upon the streptococci in the focus of infection. It was, with a blood so viscid and coagulable as was that of this patient, quite inconceivable that any lymph should transude into his tissues. It was inconceivable, also, that any transuded lymph should not clot in his lymphatics. Influenced by these considerations, large doses of citric acid were prescribed. 60-grain doses every three hours were prescribed. Six hours after the treatment had been begun lymph began to ooze into the wounds, and by next morning all the wounds had begun to bleed. The administration of citric acid was now suspended. A culture of infecting microbes having now been obtained the opsonic index of the patient's blood was determined. That opsonic index working out at 1·8, and very distinct amelioration having taken place in the patient's symptoms, inoculation treatment was postponed. There was not afterwards any occasion for immunising intervention, the patient making continuous and rapid progress to complete recovery. There is, I think, a lesson in this case which we shall do well to take to heart in connexion with all conditions where the access of lymph to the infected tissues is difficult.

AUTO-INOCULATIONS.

Up to the point at which we have now arrived the reaction of immunisation has been considered exclusively in relation to the incorporation of bacterial vaccines. A moment's consideration will, however, make clear that where, in association with a bacterial invasion of the organism, bacteria or bacterial products pass into the general lymph and blood stream intoxication effects and immunising responses similar to those which follow upon the inoculation of bacterial vaccines must inevitably supervene.

You will immediately discern that it must be by the agency of such auto-inoculations that nature achieves curative effects in bacterial infections. You will discern also that the man who proposes to combat bacterial infections by methods of immunisation must needs be familiar with the conditions under which auto-inoculations occur, and with their effects on the organism. In the absence of such familiarity the immunisator will inevitably lose his way when he sets himself (*a*) to supply the place of auto-inoculations by artificial immunisation, or (*b*) to supplement auto-inoculations where these are inadequate, or (*c*) to place a check upon auto-inoculations where these are overtasking his patient's powers of immunising response.

(*a*) *Types of infection and conditions in which auto-inoculations occur.*—We may conveniently begin by inquiring in what types of bacterial infection and under what conditions auto-inoculations take place. You will, of course, immediately discern the position of affairs in connexion with the contrasted types of 'generalised' and 'strictly localised' infections which were considered in connexion with the expectant method of treatment. In the former class of infections auto-inoculations are occurring in continuous series; in the latter they are conspicuous by their absence. In the case of the type of localised infections which are associated with intermittent constitutional disturbance we have a class of infections which is, in the respect that we have here intermittent auto-inoculations, intermediary between the other two. The auto-inoculations which have been in question up to this point are, let it be noted, what we may speak of as '*spontaneous auto-inoculations.*' In addition to these we have to consider also *artificially induced auto-inoculations.*

Taking our departure from an illuminating observation of my collaborator, Dr. J. Freeman, in connexion with the effects produced on the blood by the massage of a gonococcal joint, we have at St. Mary's Hospital made a systematic study of the conditions under which auto-inoculations can be produced in persons affected with localised bacterial infections.

We have been able to show that auto-inoculations follow upon all active and passive movements which affect a focus of infection, and upon all vascular changes which activate the lymph stream in such a focus. Evidence has been obtained of the production of auto-inoculations by massage and extirpation operations affecting tuberculous glands; by passive extension, massage, and divers surgical operations affecting tuberculous and gonococcal joints; and by scraping operations undertaken in connexion with tuberculous caries and staphylococcal osteomyelitis. Again, evidence has been obtained of the production of artificial auto-inoculations in phthisical patients when they were called upon to breathe deeply and when they were examined by percussion and auscultation. We have also in connexion with a laryngeal affection seen an auto-inoculation supervene upon reading aloud. Again, we have obtained evidence that auto-inoculation may follow upon walking exercise in the case of patients affected with tuberculous disease of the lungs or of the bones or joints of the lower extremity or with severe tuberculous epididymitis. We have also obtained evidence that in the case of patients with spinal caries auto-inoculations are induced by a change from the recumbent to the sitting posture and from the sitting to the erect posture. Lastly, we have evidence that auto-inoculations are produced both by active and passive hyperæmia (application of hot fomentations and of Bier's bandages) to limbs affected with tubercle and streptococcus respectively.

ASSISTANCE WHICH CAN BE OBTAINED FROM ARTIFICIAL AUTO-INOCULATIONS IN THE DIAGNOSIS OF OBSCURE CASES OF LOCALISED BACTERIAL INFECTION.

Let me for a moment here digress from the consideration of the therapeutic problem to consider the assistance which may be derived from the induction of artificial auto-inoculation where a problem of diagnosis confronts us. Rightly

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Open Spaces.

THE controversy regarding the acceptance or non-acceptance of the last offer made to the city by the Open Spaces Society has been somewhat prolonged and it has caused an unfortunate amount of friction. It will be remembered that the Open Spaces Society offered to the city four spaces, the total cost of which would be £12,000, towards which the society had collected £8000. The baths and parks committee was requested to report upon the matter and, as I pointed out recently, its report was decidedly adverse. The committee quite rightly considered not only the purchase cost but also the amount necessary for putting the plots into proper condition and the annual cost of upkeep. There can be no doubt, however, that as regards the two latter items it went beyond the necessities of the case, and it seemed to have missed the main point of the matter which was the necessity for securing the spaces whilst they were available under favourable conditions, even if they could not at present be elaborated and improved. Fortunately the council grasped the essential fact and whilst recognising the good intentions of the baths and parks committee it decided that as no such favourable moment for the acquisition of the spaces was likely to recur the offer of the Open Spaces Society should be accepted. One of the main difficulties which threatened to bar the way was the unwillingness of Smethwick and Handsworth to share the expenses of upkeep, in spite of the fact that the famous Black Patch, the largest of the areas offered, will be of service to their inhabitants as well as to those of Birmingham. The council, however, took the broad and right view that the unwillingness of others to bear their proper burden must not be allowed to stand in the way of anything which would be of advantage to the healthy development of the city. Wisely, however, in accepting the offer of the Open Spaces Society the council took the precaution to provide that Handsworth and Smethwick should pay their fair share of the expenses which must eventually be incurred in connexion with Hockley Brook which passes through the Black Patch. The Open Spaces Society is to be congratulated on the good work it has done in this matter. It has worked hard for the general good and even whilst the controversy over its last offer was in progress it succeeded in collecting an additional £1000 towards the purchase of the plots it offered, thus reducing the contribution of the city to £3000. The plots which it secured are not all that could be wished for, as some of the objectors to the scheme pointed out, but they will henceforth remain as open spaces and as "lung" areas in crowded districts.

Warley Model Village Scheme.

Mr. A. M. Chance has been attempting to found a model village on coöperative principles on a plot of land at Warley for which he holds an option till the end of September next. To make the scheme a success it is necessary that there should be 500 subscribers willing to take up plots. At present only about one-tenth of the requisite number have seen their way to join the scheme and unless much more progress can be made in the next few days it is probable that the plan will have to be given up, in which case what might have proved a very interesting and instructive experiment will not be made. Apparently one of the main difficulties would-be applicants find is that of providing the full amount of the cost in the necessary time. In connexion with this Mr. Chance stated that an insurance company was willing to take part on the following terms. Presuming the applicant to be 35 years old and the house and land which he was to acquire of a total value of £300, the company would lend £240, provided the applicant insured under a 20 or 25 years' endowment policy for £240, in which case the interest on the £240 and the premium on the endowment policy would amount to an annual total of £18 17*s.* 3*d.* If these are the best terms that can be obtained the probability of the necessary number of subscribers coming forward seems small.

Sleeping Accommodation for Railway Navvies.

It appears that in association with the extension of the Midland Railway from Water Orton to Kingsbury no proper sleeping accommodation has been provided for the 300 navvies employed on the work and as a result many of them have had to sleep in the open or in damp and unsatisfactory shelters. Such a condition of affairs obviously contains the germs of a definite danger to the public health and is a state of affairs over which authorities should have a control that appears to be entirely lacking. When local accommodation is insufficient the contractor should be under obligation to erect temporary buildings. Such buildings being temporary structures it would only be necessary that they should easily be kept clean and dry, but such simple precautions might well serve to avert serious danger to surrounding populations.

The Necessity for a Sufficiency of Attendants at Public Baths.

Quite recently a boy died suddenly in the Victoria-road baths. It was proved that death was due to syncope and that no assistance would have been of any use in this special case, but the Aston Baths Committee has wisely taken the warning and has arranged for an additional assistant, so that some person can always be present when the swimming bath is in use. This is a precaution which should be taken at all public swimming baths, for the danger of accident is always greatest when one person alone is using the bath, as he may at any moment be seized with cramp or may injure himself in diving, and in either case be quite unable to call for assistance.

Health of the City.

Though in a generally satisfactory condition, the death-rate for the second quarter of the year being 15·8 as contrasted with 16 in the corresponding period of 1906, and the death-rate for the week ending July 27th being only 11·9 per 1000, still the city is suffering from an excessive amount of measles and scarlet fever. The scarlet fever is of a mild type but measles has been more than usually fatal and the zymotic death-rate of 2·09 per 1000 for the second quarter is relatively too high. Everything is being done to prevent the disease spreading, but the preventive measures hitherto developed are not proving adequate.

August 12th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Bolton's Water Supply.

At the meeting of the Bolton town council on August 7th Dr. J. Thornley, medical officer of health of the Halliwell district of the Bolton Union, stated that the acidity of the water at present was such that it had become a great danger. Several cases of lead poisoning had already occurred. Some time ago the Local Government Board after an examination of the water said that certain measures must be taken to do away with dangerous elements. Some steps were taken but they were inefficient. Dr. Thornley considered that it was a mistake to have the water analysed by an outsider when the medical officer "was the party responsible to the Local Government Board." He advised that men should be employed to look after the pond weed at the reservoirs. An alderman and another member of the council deprecated public discussion and considered "that if Dr. Thornley had been a man of discretion he would not have opened his lips on the matter." One of them acknowledged that there had been two cases of lead poisoning but said "they did not arise from any arrangement for which they were responsible." It is certainly unwise to attempt to ignore this dangerous acidity of a public water-supply. There have been so many instances of serious outbreaks of lead poisoning from moorland gathered water that an attempt to hush up the matter seems almost criminal. Even if the true state of the case is fully made known a little wholesome alarm will only make people rather more careful to see that plenty of water is run off from the pipes before any is used for cooking or drinking. If they are left in ignorance of the risk run when this acidulated water is used after standing for some time in lead pipes more mischief will follow than any brought on by the fear of lead poisoning.

Platt Hall Estate.

In a southern suburb of Manchester there is a prospect of acquiring an estate of 77 acres or thereabouts, fairly well timbered and with a house. At a town's meeting held the other week a resolution was passed affirming that it was desirable that the city council should acquire it for public use as a park if it could be obtained at a reasonable price. The matter was discussed at the council meeting held on are manufactured in the tissues at the seat of inoculation it will be obvious that the conditions for successful immunisation will be less favourable when the vaccinating elements are thrown into the circulating blood than when they are inoculated directly into the tissues. In the latter case they will come into application upon the tissues in a concentrated form, while in the case where they are introduced into the circulation they will come into application upon the tissues only after they have been diluted by the whole volume of the circulating blood. It is accordingly not irrational to assume that there would be a possibility of a septicæmic patient deriving in this respect advantage from the inoculation of bacterial vaccines. Let us suppose it granted that from the point of view of his immunisation such a patient might derive advantage. There would still remain the objection that the inoculation of bacterial vaccines might aggravate his intoxication. The rejoinder to this objection is, I think, suggested by the consideration that local toxic effects on the tissues—such as are produced by the subcutaneous inoculation of vaccines—and a local elaboration of bacteriotropic substances—such as we infer to follow upon inoculation—would be inexplicable apart from a holding back of the toxic substances in the tissues. Conformably with this a much smaller intoxication effect would result from the incorporation of an aliquot quantum of vaccine into the tissues than from the inoculation of that same quantum of vaccine directly into the blood stream. I would put it to you in view of these considerations that the question as to whether vaccine-therapy can or cannot be successfully employed in connexion with septicæmic disease is a question which ought not to be prejudged. It is a question which can be decided only by experiment.

With this discussion I have at last brought to a close my exposition of the main principles of vaccine-therapy so far as these are at present clear to me. You will, perhaps, expect me to say in conclusion one or two words on the subject of the results which have been achieved by the application of this method in actual practice.

ON THE RESULTS WHICH HAVE BEEN ACHIEVED BY VACCINE-THERAPY.

The evidential methods which an author can employ to establish the efficacy of a new treatment are, as consideration will show, the following: (*a*) he can publish examples of refractory cases successfully treated; (*b*) he can publish—where such become available—examples of desperate cases successfully treated; (*c*) he can—where he has treated a sufficiently large number of cases—publish the complete series, giving the particulars of each case and the results of the treatment; and (*d*) he can—if he should be fortunate enough to enlist the interest of other workers—commit it to these to furnish definite proof of the efficacy of his method.

Let me try to bring out to you the strength and weakness of each of these evidential methods.

The evidential value of a number of refractory cases successfully treated lies, as you will discern, in this: that where success has been achieved in connexion with a number of such cases the idea that the results can be due to spontaneous cure may be dismissed. There attaches, however, to this class of evidence always a possibility of doubt, inasmuch as, even when the author is citing a consecutive series of successful cases, the reader will find a difficulty in believing that these were typical cases. He may incline to the view that all the cases cited may have been exceptionally fortunate cases where nature was in each case good enough to step in to effect a spontaneous cure.

In the case where the author has cited desperate cases successfully treated somewhat similar criticisms apply. It will be manifest that if the cases cited by the author were in reality, as he deems, cases in which a cure could not possibly have been effected by the unassisted efforts of nature, the successful event of these cases furnishes complete proof of the efficacy of the treatment. It must, however, always be borne in mind that, in the absence of the evidence of his own eyes to the desperate condition of the patients, the reader may find it easier to believe that the author was mistaken in regarding his cases as desperate, than to believe that that author's treatment can have been effectual in desperate cases.

Quite other are the criticisms which would apply to a statistical record of the event of treatment in a consecutive series of cases. It is, I think, not open to doubt that, apart from any incidental value which it might derive from the inclusion of refractory or desperate cases, such a series of cases would acquire value only *if it were placed over against* a series of quite similar control cases. Now a series of untreated cases such as would serve the purpose of controls cannot in practical life be obtained. For such a series of untreated controls there would therefore have to be substituted, as the only possible alternative, a series of cases treated by another method, and by another practitioner. Now if this were done the scientific issue would immediately be confused, not only by doubts as to the comparability of the two series of cases, but also by the question as to whether the therapeutic method which was applied in the control cases was hurtful, innocent, or beneficial, and above all it would be confused by the question of personal competition. If you will consider what confusion would in this way be introduced into the issue which we are here concerned to resolve, you will, I think, understand the motives which influence me when I say that I do not propose, either here or elsewhere, to supplement by any attempted statistical proof that presumptive proof of the efficacy of vaccine-therapy which I claim to have already furnished by the citation of numerous refractory and desperate cases successfully treated by the inoculation of bacterial vaccines.

And if you have completely entered into my thought you will appreciate that if I have in this lecture restricted myself in the main to an exposition of the principles of vaccine-therapy, leaving over so short a time to the discussion of the practical results which have been achieved, this has not been without set design. You will understand that it has been done because I felt that, if I could enlist your interest in the method of vaccine-therapy, if I could show you upon what principles it proceeds, and if I could induce here a scientific worker and there a scientific worker to embark upon the task of mastering and carrying out patiently the somewhat delicate technique which is, in my opinion, essential to the proper exploitation of vaccine-therapy, I might perhaps be taking the shortest way to procure for you a verdict on the practical efficacy of the method which should be free from the fallacies which attach to any 'author's account.'

Let me, in conclusion, for I may hereby perhaps induce others to make proof of the method, attempt very briefly to summarise for you my personal experience of the practical results of vaccine-therapy. You will, of course, appreciate that no one formula could possibly apply to all the various forms of infection which are encountered. It will be well for us to commence with the type of bacterial infection which presents the simplest therapeutic problem.

(*a*) *Type of Infection where a Single Species of Micro-organism has Penetrated into the Interior of the Body and has established itself in one or more Foci without causing any considerable Destruction of Tissue or Constitutional Disturbance.*

Typical examples of this type of infection are to hand in the case where tubercle bacilli have effected a lodgment in lymphatic glands, and in the case where staphylococci have penetrated into the subcutaneous tissue causing as yet only suppurative (furuncular) as distinguished from necrotic (carbuncular) changes. In this type of infection all but uniformly successful results have in my experience been achieved by vaccine-therapy. In the case of furunculosis those results are achieved within a period of a few *days*. In the case of tuberculous infection of the lymphatic glands the period required has varied, according to the extent of the infection and the individual patient's power of immunising response, between five weeks and 18 months. It has on the average ranged about six months.

What applies to tuberculous infection of the lymphatic glands applies in a general way also to tuberculous infection of the testicle, and to simple tuberculous infection of the kidney and urinary passages. It applies also—but on this question I speak with a reserve imposed upon me by a very restricted experience—to early cases of tubercle of the lungs.

(*b*) *Ulcerative Type of Infection.*

In my experience this type of infection—a type which is met with in connexion with the breaking down of nodules in the deeper tissues, and in connexion with the penetration of superficial infections into those tissues—does not differ with respect to its tractability to vaccine-therapy from the type of infection last considered, except only in the case where secondary infections have supervened. If anything—given the case where secondary infections have either been avoided or been successfully combated—an open ulcer is pening the hospital, mentioned that the cost of the large number of repairs and improvements, amounting in all to 600, had been handsomely defrayed by Lord and Lady Keith. After the opening all those present were invited inside to see over the building.

The Epidemic of Enteric Fever at Peterhead.

During the past week 25 cases of enteric fever have been notified to the medical officer of health at Peterhead, making a total of 313 cases since the commencement of the outbreak. Of these, 110 have been treated in the hospital and the remainder at home. 50 cases have been discharged from the hospital as well and one has died during the week. About 40 cases have fully recovered. During the month of June three cases of enteric fever were reported in Aberdeen, one of which proved fatal. The source of infection of the fatal case was apparently Peterhead. In each of the three cases the infection was traceable to a visit to Peterhead.

Death of James Henderson Mackay, M.A., M.B., Ch.B. Aberd.

The death is reported in Manchester of Dr. James Henderson Mackay. Dr. Mackay was a native of Aberdeen and was educated at the Grammar School and the University of Aberdeen. He graduated in arts in 1695 and in medicine in 1899. For a time he was on the staff of the Royal Lunatic Asylum, while for the past two and a half years he has been in practice in Manchester. Dr. Mackay's end came suddenly. After a hard day's work he retired to rest in the best of health and spirits. In the early morning he was found unconscious and soon passed peacefully away, heart failure being the cause of death.

August 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Health of Belfast.

AT the usual monthly meeting of the Belfast corporation, held on August 1st, it was reported that between June 16th and July 20th 181 cases of infectious disease had been notified—viz., 24 cases of typhoid fever, 44 of scarlet fever, 22 of simple continued fever, three of puerperal fever, 14 of diphtheria, 1 of croup, 25 of erysipelas, and 48 of cerebro-spinal meningitis. The death-rate during the five weeks ended July 20th was 18·3. There is a decrease in typhoid fever and cerebro-spinal meningitis. During the week ended July 27th two cases of cerebro-spinal fever were notified, as compared with seven in the previous week. In the same period there were 12 deaths from the disease. Since the previous meeting of the committee, July 25th, five cases of cerebro-spinal fever were notified. There are still 20 cases of cerebro-spinal fever in Purdysburn Fever Hospital.

Rainfall in Ulster in July.

At Seaforde, Co. Down, during July rain fell on 13 days to the amount of 2·23 inches and the total for the past seven months is 22 65 inches, which is more than in the same time in 1906 (17·93 inches).

The Treatment of Consumption in Belfast.

The Local Government Board has approved of the arrangement made between the committee of the Forster Green Hospital and the corporation of Belfast, under which 25 beds are to be placed at the disposal of the corporation for consumptive patients at a charge of 35*s.* per bed, for a period of ten years. In its letter the Board says it trusts that it may lead to a larger effort on the part of the corporation for dealing with the prevalence of pulmonary consumption in Belfast, and adds, "While the Board would have been glad if the corporation had seen their way to propose a more extensive scheme for the treatment of consumptive patients, in view of the extensive prevalence of pulmonary tuberculosis in Belfast, they consider that the delay and other difficulties which might attend the negotiations for such a scheme would not justify them in withholding their approval of the present proposal."

North of Ireland Veterinary Medical Association.

At a meeting of the above association, very largely attended, held in the City Hall, Belfast, on July 26th, the President (Mr. J. J. Ross, M.R.C.V.S., of Belfast) being in the chair, Professor A. E. Mettam, B.Sc., M.R.C.V.S., President of the Royal Veterinary College of Ireland, read a paper on the Veterinary Surgeon as an Officer of Public Health. Having referred to the scientific education now needed by veterinary surgeons he pointed out that his study of disease extended far beyond the cause and the course; indeed, it became a study of economics, either as affecting the owner, the municipality, or the State. With reference to his duties as an official assisting those dealing with the public health, the veterinary surgeon should be the chief inspector of meat, and should be responsible for the inspection of all cowsheds and all animals producing milk for human consumption. He should be the official to whom all practising veterinary surgeons should notify infectious diseases in their own area. He should be consulted on every occasion when buildings were being erected for animals, such as stables, cowsheds, kennels, &c. As chief inspector of meat he should be responsible for all meat exposed for sale. Both the veterinarian and the medical officer have their own places. The medical official should be responsible for the health of the community, while the veterinarian should be his chief lieutenant, taking charge of that portion of the work of the public health committee relating to animals, no matter whether they were to produce flesh for food or milk or whether they were kept for work, profit, or pleasure. Sir John W. Byers, who had been specially asked to introduce the discussion on the subject of the paper, after congratulating the members of the veterinary profession in the north of Ireland on the step which they had recently taken in forming a new society, and having spoken in terms of the warmest praise in reference to Professor Mettam's very suggestive paper, said that veterinarians and medical men had now great responsibility in their hands as regards questions of public health, and in nothing was this more apparent than in the care that was now demanded as to the purity of our food supplies, especially meat and dairy produce. He said he was convinced that to be fair to farmers, traders, and consumers things would never be right until inspection of these products was imperial, universal, and of the same type or method, done by thoroughly trained veterinary surgeons appointed by the State and responsible to the State; and municipalities should not admit into their markets meat or dairy produce which had not passed a State inspection. In America the laws of such inspection were federal and the whole arrangement was imperial in Germany. He spoke of the universal attention that was now being called in all countries to the importance of a State control of the milk-supply and quoted the very important conclusions in the second interim report of the Royal Commission appointed to inquire into the relations of human and animal tuberculosis, which showed so clearly that tuberculosis in the cow was a fruitful source of disease and death in man. With reference to the practical remark made by these commissioners: "Our results clearly point to the necessity of measures more stringent than those at present enforced being taken to prevent the sale or the consumption of such (tubercular) milk," Sir John Byers advocated that these increased powers should be given to the State so that a uniform and universal system or line of action might be adopted both in town and country. In dealing with such serious problems of public health the medical and veterinary professions would have to work together so as to bring about a state of affairs in which not only would the cattle used in dairying be free from any acute or chronic disease, but in which the *milkers* and all others directly in charge of the dairies would also be clear of any form of infectious illness. This was the ideal they must all strive to obtain, and it was based upon the teaching of science and experience. Mr. J. McKinney, M.R.C.V.S., Dublin, moved, Mr. J. A. Thompson, F.R.C.V.S., *seconded*, and Dr. A. Dempsey supported, the following motion, which was unanimously carried :—

> That a system of inspection of meat and dairy produce should be established by the State, to be applied with equal thoroughness and impartiality in all districts; that such inspection should be conducted only by trained veterinarians and appointed by the State; that municipalities should be empowered to exclude from their markets all meat or dairy produce, whether of native or foreign origin, which had *not passed the State inspection.*

On the motion of Sir Otto Jaffe (ex-mayor of Belfast and member of the public health committee), seconded by Mr. H. McConnell, M.R.C.V.S., and supported by Dr. S. Agnew (medical officer of health of Lurgan) and Mr. G. L. St. George (Lisburn), the following motion was carried :—

> That in the opinion of this meeting at an early period the veterinary surgeon should report direct to the health committee and not to the medical officer of health.

A Clinical Lecture

ON

STRICTURE AND TRAUMATISM OF THE VERMIFORM APPENDIX.

WITH A NOTE ON FOREIGN BODIES IN THE APPENDIX.

Delivered at St. Thomas's Hospital on May 30th, 1907,

By WILLIAM HENRY BATTLE, F.R.C.S. Eng.,
SURGEON TO THE HOSPITAL.

Gentlemen,—A narrowing of the lumen of the appendix is very commonly met with when it is opened after removal for symptoms of disease. A small part may be involved or nearly the whole length. Again, there may be found more than one stricture which has interfered with the escape of the contents of the appendix. These strictures may be divided into two great classes—the organic, where there is gross change in the appendix narrowing its lumen, and the functional, in which the appendix is not grossly diseased. In the first class the stricture is most frequently due to ulceration of the mucous membrane, which has subsequently healed and the scar contracted. In a less common variety the stricture is due to a cellulitis of a segment of the appendix, where the mucous membrane is not destroyed. In this case the fibrous tissue is between the mucous membrane and the peritoneum. In a third variety the narrowing of the appendix may be due to the contraction of peritoneal adhesions or to the presence of pathological processes (e.g., carcinoma of the cæcum) which have secondarily involved the appendix. The cases in which the lumen of the appendix is narrowed in one place, though the organ is healthy, fall into two great classes. In the first the appendix is kinked or bent, which functionally narrows its lumen, though it is not obviously diseased. Oblique insertion of the appendix into the cæcum also comes under this head. In the second class the appendix is pressed from without, and its contents dammed up, as in carcinoma of the cæcum.[1]

It may be stated that cases of stricture are not often found without a complication of chronic inflammation of the wall, so that the appendix with a strictured lumen and a stiffened wall is very greatly hampered in its attempts to empty itself. An appendix so circumstanced is especially liable to trouble, for a recrudescence of inflammation may cause a complete closure of the passage and a rapid accumulation of inflammatory fluid and pus beyond, which will escape by ulceration or gangrene of the wall of the appendix, giving rise to the most serious inflammation of the peritoneum with which we have to contend. A definite organic stricture is found in more than half the cases accompanied by local suppuration in the surrounding peritoneum. Less acute processes may be followed by the formation of a distended appendix beyond the stricture into a mucocele or empyema of subacute character.

Clinical Signs.

You will naturally want to know the signs, if there are any, which enable us to recognise a strictured appendix before removal from any other form of disease of that part. In the majority of instances it is impossible because a single attack of appendicitis due to stricture resembles one caused by inflammation of the part having a different cause, but when you are confronted with an attack which is more severe than others which have preceded it, whilst the others had given evidence of increasing severity, as they increased in number, then you will not be far wrong if you venture the opinion that the appendix is strictured. Some will have had vomiting as an initial symptom, whilst in others the pain will have been severe, whilst frequently there will be no local swelling noticed until the latest and most severe attack. Not uncommonly you will find in the situation of the appendix a thickening or lump which indicates the point where inflamed omentum became adherent to the appendix and closed a perforation which had occurred in it, as usual, beyond the stricture. In these cases the stricture was probably situated towards the distal end of the appendix.

It is of interest to note the severity of the stricture in some cases in which the appendix is removed after a single attack of inflammation. The patient may positively affirm that the attack from which he has just recovered is not only the only one he has had but that he has never had any trouble before in the abdomen. This may be confirmed by the friends through ignorance of the real facts of the case.

There is here a long appendix which I removed on April 30th from a man, aged 19 years. It is, as you can see, tightly strictured at the proximal end, and at the time of removal was tensely distended with about five drachms of fluid fæcal matter and inflammatory products, so that it extended like a bent fore-finger from its origin to an attachment in the retrocæcal fossa. Here it was buried and firmly bound down by old adhesions. Not far from the proximal end was a patch of lymph underneath which was the discolouration of impending gangrene. All muscular contractility seemed to have gone from this appendix, and when emptied the walls were thin, soft, and flaccid. This was 20 hours after the commencement of symptoms and shows the result of excessive distension. Here it was quite apparent that there had been pre-existing trouble about the appendix of which we could get no history. It was stated that he had had "abdominal chills," but never any pain with them. A more accurate history was obtained later, making it very probable that the patient had made light of his troubles during "the chills" for fear of alarming his parents; and that they were ignorant of the true facts of the case. Indeed, from his account he had suffered a good deal during the previous two and a half years. The first attack of definite abdominal trouble lasted a week and was called "typhoid"; a more severe illness had occurred five months before the removal of the appendix, but before and since this illness he had suffered considerably at times from "stomach-ache," especially on exertion. You can imagine the effect on the peritoneum of this quantity of fluid had it escaped into the peritoneal cavity; luckily we were able to prevent this and the case ran a normal course.

Several cases could be cited which show this want of proportion between the extent of the disease and its apparent duration. One of them was that of a medical man who is a careful and unprejudiced observer. In November, 1904, he had an attack of pain in the abdomen running down to the penis and groin but not followed by any alteration in the character of the urine. It lasted a few hours and he did not take his temperature. On Friday, March 3rd, 1905, he had another attack lasting longer. Next day his temperature was 101° F. and on the day after that 99°. He had no vomiting in either attack but much pain, whilst during this illness he had noticed some swelling. On the former occasion he went about doing his visiting but this time he was not permitted to do so. He came to see me on the 7th and presented a tender swelling of about the size of the forefinger just above Poupart's ligament on the right side. When the appendix was removed on March 16th it was found adherent to surrounding parts, whilst the omentum was attached to, and covered, a recent perforation. It was unusually thick walled and when opened we found in it a stricture which almost obliterated the lumen to within three-quarters of an inch of the extremity, beyond which was the perforation. This stricture was about three-quarters of an inch long. He has had no abdominal pains since.

Concretions and their Effects.

In connexion with the subject of stricture of the appendix it would, perhaps, be well to discuss briefly the causation of such a condition, more especially from the point of view of the possibility of traumatism as an exciting cause. For this purpose we must consider the various bodies which form in, or enter, the appendix from the large bowel. The husband of one of my patients advised his wife to have the appendix searched after removal for anything she had lost during the preceding six months. Certainly the list of things which find their way into it is a very large one, but we may exclude from it, so far as our purpose to-day is concerned, the intestinal parasites It is not usual to find foreign bodies forming part of a concretion; when they do so the combined result is generally that of an ordinary concretion. These concretions are composed of fæcal matter which has undergone a hardening and excited a secretion of mucus from the surrounding glands. In experimentally isolated loops of intestine a somewhat similar process can be seen. Structurally, these calculi sometimes have for a nucleus some foreign body, but much more commonly a harder fæcal

The Medical Academy at Düsseldorf.

THE recent opening of the medical academy at Düsseldorf was an event of some importance and was attended with considerable display. These medical academies have been already referred to in these columns and it may be remembered that they are institutions of quite recent origin having a two-fold object. In the first place they will import a new feature into medical study by introducing newly qualified men to the practical side of medicine more than is done at the universities. After the university medical curriculum has been completed and the State examination has been passed, the practical year which is required by recent regulations may be spent at the academies. Their second purpose is to supply the medical practitioners of the district with opportunities for post-graduate study. Up to the present time the only medical academy has been the one at Cologne; there was an intention of establishing a second one at Frankfort but the project failed because of the opposition of the medical profession in that city. The Düsseldorf Academy is the first for which clinics and lecture-rooms were specially built, because at Cologne the existing municipal hospitals were adapted for teaching purposes. The structural and other arrangements are described as excellent and the clinical material will certainly be abundant. A well-known surgeon, Professor Witzel, formerly of the University of Bonn, is the director of the new academy, while the teaching staff includes Professor Schlossmann in the subject of pædiatrics and Professor Lubarsch in the subjects of pathology and pathological anatomy. The medical academies at Düsseldorf and Cologne will probably be for a long time the only institutions of their kind.

Professor von Leyden's Valedictory Lecture.

Professor von Leyden, who is vacating the post of ordinary professor of clinical medicine and of director of the medical clinic held by him for 32 years, was the object of many demonstrations of sympathy and esteem on the delivery of his last clinical lecture. Many of his colleagues and former assistants as well as the staff of the clinic were present in addition to the students, and representatives of each group made short speeches appropriate to the occasion. Professor von Leyden was deeply impressed by this unexpected incident, and in acknowledging the compliments paid to him by the various speakers he gave a short history of the progress of clinical medicine since the days when as a student he listened to the clinical lectures of the late Professor Schönlein. Professor von Leyden's successor, Professor His of Göttingen, will enter on his duties at the beginning of the winter semester.

The Hospitals of Berlin.

The hospital accommodation in Berlin has been considerably increased during the last 12 months, especially by the completion of the new Virchow Hospital, containing about 2000 beds. Formerly it was a common occurrence for the daily newspapers to mention that owing to the crowded state of the hospitals it was necessary to refuse patients even when suffering from serious illness, and such patients had to go from one institution to another in search of a vacancy. The Statistical Office has recently published a report on the hospitals for the year 1904. There were then in Berlin 24 public and 68 private hospitals and sanatoriums, containing 9156 beds, each of which was on an average occupied during 298 days per annum. The number of beds had increased by 700 since the year 1903. With respect to the public hospitals, it is stated that 59,842 patients were discharged from them, that 9412 died, and that this relatively high mortality was partly due to the mortality in the infants' department. It must be remarked that the above statistics include only the hospitals of the city of Berlin without the newly opened Virchow hospital, and, of course, without the hospitals in the suburbs. The suburban local authorities have recently done good work in the way of hospital accommodation; some of their hospitals, such as the Charlottenburg and the Schöneberg hospitals, are constructed in complete accordance with modern requirements and their general arrangements are excellent.

Sanatoriums for Tuberculosis in Germany.

According to the report of Dr. Nietner, general secretary of the German central committee for the prevention of tuberculosis, there are at present in Germany 87 public and 35 private sanatoriums for tuberculous patients, a number considerably in excess of those existing in all the rest of Europe. There are also in course of construction 11 sanatoriums containing 800 beds. For tuberculous children there are 17 sanatoriums with 650 beds and for scrofulous children there are 67 with 6092 beds. Finally, 117 Fürsorgestellen (dispensaries), of which 31 are under municipal control according to Putter's system, 67 Walderholungsstätten (places where the patients spend the day, returning home in the evening), and two rural colonies complete the organisation controlled by the committee.

Discredited Medical Authors.[1]

The Union of the German Medical Press at its last meeting decided to compile a register of those authors who receive money for writing articles recommending new chemical compounds and other preparations, this being, of course, done in the interest of the chemical manufacturers concerned. In future the works of these authors will neither be accepted for insertion by the journals belonging to the union nor referred to. The first register has been issued and distributed to the members. The committee of the union hopes by this proceeding to place some restriction on an abuse which is inimical to the interests of the medical press and of the public as well.

August 12th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Prevention of Venereal Diseases.

THE National Committee for Preventing the Spread of Venereal Diseases recently held a conference which has been much commented upon. The opinion was expressed that the examination of prostitutes requires to be thorough, as all secretions of gonorrhœal cases must be scrutinised for gonococci after apparent recovery. The segregation of prostitutes in the so-called "bordels" or places under police supervision is strongly condemned, although this system is in full operation in Budapest. No proof is given that any special advantage is obtained thereby, as the factories in which there is so much female labour counterbalance the good. Professor Neisser has asserted that he is inclined to believe that everything that excites the passions or encourages unchastity, such as alcoholic excess, suggestive theatrical performances, and obscene literature, will increase the evil and that more supervision of our factories with perfect isolation of the immoral will go far to reduce it. To prevent the spread of syphilis immediate medical treatment is essential, but whether this should be provided free of charge is doubtful. Róna thinks that every member of the medical profession should have special instruction in all the skin diseases connected with syphilis in order to recognise it early and to check its further spread at once.

Surgical Teaching at Budapest.

Budapest is being resorted to by foreigners for the study of surgery, and this is becoming more evident every year. If those who go to study surgery at Budapest would first take the trouble to find out the conditions which obtain at that centre much vexation could be avoided. When it is remembered that surgeons like Professor Dollinger, Professor Réczey, Professor Herczel, and Professor Navratil have as many as 10 or 12 assistants each and that these gentlemen stand round the operating table, it will be easily understood that the spectators in the theatre reap but little benefit from their view of what is going on. The reason for this great number of assistants is that in Budapest it is not considered unethical to state that fact in a somewhat prominent way on the professional card and door-plate. As a matter of fact, the most advantageous way of studying surgery at Budapest is to take out, under one of the chief surgical assistants,

A Clinical Lecture

ON

STRICTURE AND TRAUMATISM OF THE VERMIFORM APPENDIX,

WITH A NOTE ON FOREI

Delivered

...conclusion that of the appendix much trouble now than it was; in 1893 the appears for the first time in the hospital reports, only three cases being tabulated under that head, whilst last year the number was nearer 250. Cases of perityphlitis were tabulated in the medical report but were not numerous.

Why is this? We may take it the human body as a germ-carrying organism is much the same now as it has been from the earliest time; also that the bacillus coli of the individual with its potentiality for mischief has been much the same through the ages as the specimens which are captured in the digestive canal or in the peritoneum surrounding an inflamed appendix at the present day. That it was in past times a very virulent organism may be taken for granted, for cases of fulminating appendicitis were known years and years ago and have doubtless caused the hanging of more than one innocent person on the accusation of poisoning.

SOME THEORIES OF CAUSATION.

There is a general agreement amongst pathologists that appendicitis is a disease caused by the action of the germs which should normally be confined to the interior of the intestinal tract. It is only when they gain admission to the tissues outside the epithelial lining of the tract that they become dangerous and cause inflammatory changes. Is there anything in our way of living or in the food which we eat that can in any way account for the fact that they pass this epithelial barrier more frequently now? Has anything been introduced during the last 30 years or so which can be pointed to as a possible cause? We do not eat anything like the same amount of meat as our forefathers of a century ago did nor are our dinners as a rule so long. We cannot, therefore, blame butchers' meat, as some appear anxious to do, although the amount eaten may be out of proportion to the exercise taken. There is in the museum of the Royal College of Surgeons of England a small lump of solder which was found in the appendix of a soldier during the South African war, but this is probably an example of the evil of the hurried bolting of tinned meat, and the foreign body would have been detected in ordinary circumstances.

Through the kindness of Mr. Eisenmann I was enabled to make some inquiry into the value of the opinion that the enamel of cooking vessels was a likely source for particles which might perhaps lodge and damage the mucous membrane of the appendix. It has been stated that the enamelled ware has changed its character; that in the first instance it was very good, but the price was high. There was a great demand for a lower-priced article and soon this want was supplied, only the lining enamel was of inferior quality and apt to chip and crumble away during the preparation of food. A paper[4] had an article on this subject by Dr. Villaret of Posen, who, after an investigation of the subject, came to the conclusion that there was no evidence of detachment of particles which would do any harm.

The question for solution is whether there is anything which could produce a superficial lesion and yet give but little evidence of its action—something which is universally liable to be taken by old and young, rich and poor, by the child just able to move about and by the octogenarian, by the cottager on the hill-side and by the prince in the palace; something which is generally spread over the surface of the civilised earth, and something which is not likely to attract the attention of the person taking it. At one time I thought perhaps it would be found that some of the harder samples of wheat might during the process of grinding produce siliceous particles which could resist the action of the gastric juice and cause trouble in this way. Mr. Jago, the well-known expert on wheats and flour, kindly called and talked the question over with me; he considered that even the hardest of Arabian wheats are finely ground by the rollers now used and the product satisfactorily screened. Some time ago Mr. J. Bland-Sutton[5] some cases in which the appe foreign bodies in the intestine attack of inflammation, the care which was exercised in the that the attack foreign substances. Before wheat is passed the only rollers it is passed over magnets, which extract from it all pieces of iron which have found their way into it during its journey from the field to the mill. Other foreign bodies are also extracted.

A POSSIBLE CAUSE FOR THE FORMATION OF STRICTURE.

The question then presented itself, Is it possible that during the process of grinding the flour some foreign substance has been or can be introduced? I have been informed that roller-milling was started in Austria many years ago and that in the first instance porcelain rollers were employed; it was then taken up in America and steel or iron rollers were substituted; that the primary rollers are fluted in order that they may exert a more crushing effect on the hard wheat which is ground by them; and that in a variable time this fluting is worn away and a fresh roller has to be put in. There is a difference of statement as regards the durability of these rollers, which it is difficult to understand, excepting on the supposition that they vary much in their hardness. Of course, there is an immense amount of flour put out by every mill as a result of the work of any two of these fluted rollers in comparison with the fragments of steel or iron which would come away at the same time. Moreover, these fragments would necessarily be widely scattered, and if of any appreciable size only present in the flour which had been passed through the larger screens. I imagine that a small, irregular particle of steel or iron escaping from the faulty or worn roller might pass into the digestive tract by the mouth, it would escape destruction in the alimentary canal, and, when it had passed through the ileo-cæcal valve, fall downwards by its own weight, going sometimes into the opening of the appendix. In any situation it would come into contact with mucous membrane and probably be washed on again by the fluid contents of the part and disappear. This would not be unlikely to happen in the appendix, for a muscular contraction would follow as a reflex result of the localised irritation caused. Some abrasion of epithelium if the foreign body had lodged between folds of the mucous lining might be expected. Increased secretion of mucus would be the result and again the foreign body might be carried away in the right direction and disappear. Sometimes this abraded surface would not heal, and unusual exertion or a stretching of the cæcal wall as a result of over-eating would throw a strain on the part. The abraded surface would give the bacteria their opportunity and the added strain cause them to spread more widely when they had passed the breach. Even then the parts might recover and the patient be unaware of anything wrong, but following on the inflammation with abrasion of the mucous membrane would come fibrosis with its resulting contraction, possessing unusual importance in a canal with such a small lumen.

It is interesting to note that this lesion of the appendix is never constant in position like stricture of the urethra. Sometimes it is at the orifice, more commonly at the distal extremity, and this in appendices which resemble one another very closely and are not deformed or displaced. Of course the extent of the disease varies very much in different individuals, as does also the number of strictures. Having this theory in mind, a look-out was kept for a possible body of the kind imagined, it being thought that perhaps one might be found which had escaped expulsion, but for a long time without success.

A boy, aged 13 years, was in Leopold Ward from Feb. 21st to March 11th, 1905, for abdominal pains of 14 months' duration, worse after walking. He also gave a history of dysuria. A careful examination was made of the urinary system by means of the x rays, &c., but nothing abnormal was found in it or in any other part of the body. Advice was given against operative interference, although his mother was very anxious that something should be done. He was readmitted on March 15th because his mother brought him back, saying that he had been much worse. An attack of pain had come on after his return home and he had been sick and giddy with it. It was definitely on the right side of the abdomen, and although not severe enough to double him up, still it had been very bad and paroxysmal. There was nothing discovered to indicate the source of the pain, but at the request of his mother the abdomen was explored on March 17th. As a thickening could be felt in it and nothing else presented any abnormality the appendix was removed. It was pelvic in position but not adherent.

---

[4] Deutsche Medicinische Wochenschrift, Jan. 1st, 1904.

[5] THE LANCET, Oct. 24th, 1903, p. 1149.

the total number now available was 48. The daily average at the Thirlmere Home was 30 and the number now available was 31. Of 55 patients discharged, 46 were improved, five were unimproved, and four died. The average residence of discharged cases was 222 days. At King's Tableland 101 cases had been admitted to the Home and 100 had been discharged. Most of the patients had followed indoor trades and occupations. The treatment adopted in all cases was the open-air or sanatorium system on the principles laid down by Bodington, Brehmer, Dettweiler, and Walther. Wright's method of calculating the specific resistance to the bacillus by means of the opsonic index had recently received attention and observations on this method were now being carried out at the home. Increase of weight occurred in 91 per cent. of the cases treated, the amount added varying from 1 to 36 pounds and averaging 14 pounds each. The average increase in 55 arrested cases was 16 pounds.—The Premier of New South Wales has decided to comply with the request of a deputation from the Alexandra Hospital for Sick Children, Sydney, for a grant of £2000 to meet current expenses and for a sum of £5000 towards erecting nurses' quarters being placed on the next estimates. He is also prepared to increase the amount on the estimates which may be earned annually as £ per £ subsidy from £2000 to £4000, provided the hospital continues the supervision of State children taken to the hospital for survey and will admit for treatment any among them who require it.—A vacancy has occurred in the position of honorary indoor surgeon at the Royal Prince Alfred Hospital, Sydney, owing to the completion of the term of service of Mr. C. P. B. Clubbe. Applications are invited for the post.—Mr. S. A. Ewing has been appointed specialist for diseases of the ear and throat at the Alfred Hospital, Melbourne, in succession to the late Dr. J. Cox.

Care of Inebriates.

The Victorian Government has completed arrangements for establishing an inebriate home at Lara, a small agricultural village some 36 miles from Melbourne, which was opened on July 1st. The New South Wales Government, on the other hand, has abandoned the project of establishing inebriate homes in the islands in the Hawkesbury River and has not yet made provision for imprisoning confirmed drunkards in the Darlinghurst Gaol, as it proposed in lieu thereof.

Friendly Societies and the Medical Profession.

The eighteenth annual meeting of the Friendly Societies' Association of New South Wales was held in Sydney when the annual report stated that the membership of the 18 affiliated societies was 101,463. The total funds stood at £960,668. The amount of sick pay paid was £83,375 and the amount paid for funeral benefits was £24,049. Other figures were: amount paid for medical benefits, £87,465; total receipts, £390,465; total expenditure, £314,491; increase of income over expenditure, £75,974; and interest earnings, £34,324. The figures were described to be "indicative of a healthy condition, though not yet equal to the figures of Victoria and New Zealand." The report further stated that the relations existing between the medical fraternity and the friendly societies were assuming proportions inimical to the best interests of the societies and that the publication of the form of agreement with the friendly societies, as finally adopted by the council of the British Medical Association, "put a kind of cap upon everything." At the request of this Association a conference was arranged and after two sittings its business had been determined. The proposed agreement comprised some ten sections and several subclauses. The final paragraph in the agreement where the wage limit came in was the rock upon which it was supposed the conference would materially differ. The medical officers were resolute for a wage limit to be fixed at the rate of £200 per annum. The friendly societies' representatives were equally opposed to any wage limit. Finally a compromise was arrived at, to be referred to the various societies, as follows: first, the adoption of the principle of the £200 wage limit at joining; secondly, subsequently to joining the wage limit to be increased to £300; and thirdly, members earning above £300 to be debarred from medical attendance; this wage limit not to be retrospective. The report was adopted. The honorary secretary urged the societies to see that they were not taken by surprise by the medical men. He was strongly opposed to the wage-limit, especially in country districts. He also said that in the metropolis opposition to the British Medical Association was being organised, a new society of medical men being formed, to be known as the "Australian Medical Association."

Strychnine in Mistake for Quinine.

A woman at Wallsend, New South Wales, has died suddenly after taking a powder supposed to be quinine. The Government analyst deposed that the packet labelled quinine consisted wholly of strychnine hydrochlorate, and the stomach of the deceased woman contained strychnine. A son of the deceased deposed to purchasing the quinine and seeing the druggist write the label. He carried it straight to his mother, who then took some of the powder. The druggist who dispensed the powder admitted that the packet came from his shop and that the label was in his writing. He maintained that when it left the shop the packet contained quinine only. He could not possibly have dispensed strychnine hydrochlorate as he never had it in the shop, except in solution for dispensing purposes. The inquest lasted six days. In the result the coroner said that the druggist must be held responsible and accordingly committed him on a charge of manslaughter.

Poisoning by Carbon Monoxide.

An inquest was held in Sydney into the death of a woman who was found dead in her bed. It was shown that an escape of gas had occurred. The Government analyst stated that the gas supplied by the Australian Gas Light Company contained over 11 per cent. of carbon monoxide on account of the addition of water gas, while the percentage in English coal gas was about 6 per cent. The carbon monoxide being odourless was very dangerous to life when an escape occurred. Dr. A. A. Palmer said that the cause of death was poisoning by carbon monoxide and the excessive percentage of it in the illuminating gas accelerated the death.

Action for Malpraxis.

Dr. W. Trethowan of Perth, Western Australia, was recently defendant in an action in the Supreme Court of Western Australia and won the case. The plaintiff alleged that he sent for Dr. Trethowan to attend his son. Dr. Dawson, Dr. Trethowan's assistant, came and said that the boy had influenza. Subsequently Dr. Trethowan attended and advised his removal to hospital, where he died from typhoid fever. The patient was differently treated in the hospital. Mr. G. Cuthbert was called for the plaintiff and said that he had been subpœnæd against his will. He had been told by the counsel for the plaintiff that a certain medical man had made certain statements and he was asked to bear them out. He replied that he could not do so with truth. The judge expressed surprise at a medical man being dragged into the witness-box in such a manner. Dr. Stewart and Dr. Tafe were called but failed to respond and the case for the plaintiff closed. For the defence Dr. Dawson said that when he first saw the boy he thought that the illness was influenza, but subsequently found that it was typhoid fever. He then advised removal to hospital but the boy's mother objected. Dr. Trethowan said that when he saw the boy he regarded the case as one of typhoid fever and urged removal to hospital. The judge said that there was not a particle of evidence to show that Dr. Trethowan was either negligent or unskilful, and the jury completely exonerated both Dr. Trethowan and Dr. Dawson.

July 15th.

Medical News.

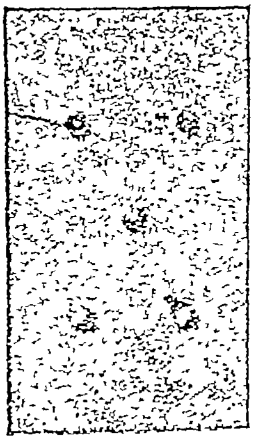
UNIVERSITY OF LONDON.—At examinations held recently the following candidates satisfied the examiners:—

PRELIMINARY SCIENTIFIC EXAMINATION.

PART I.

Inorganic Chemistry, Experimental Physics, and Biology.—William Daniel Arthur, Cardiff Intermediate School; Joe Edward Ashby, Epsom College; Vicente Atienza, Guy's Hospital; Cuthbert H. Attenborough, King's College; William Rawson Barlow, Middlesex Hospital; Grantley Barratt, London Hospital; Thomas Izod Bennett, Guy's Hospital; William Butterfield, South-Western Polytechnic; Thomas Philips Cole and David Arwyn Davies, Guy's Hospital; Isaac Milton Davies and John Prosser Davies, University College, Cardiff; Richard Denis Davy, London Hospital; Minnie Constance Dence, London (Royal Free Hospital) School of Medicine for Women; Macormack Charles F. Easmon, Epsom College; William Henry Edmunds, University College, Cardiff; George free in the appendix it apparently causes no injury; probably when incorporated with a concretion it chiefly produces an effect by the increased weight which it adds to it. The history of one such case is as follows. A woman, aged 60 years, was seen for the first time on Feb. 22nd, 1906, and the appendix removed. She was a stout patient with a history of bilious attacks, and jaundice on one occasion. Four days before operation severe abdominal pain came on when sitting quietly in church, ascribed to colic from eating dressed crab on the previous evening. The abdomen was greatly distended and motionless. Operation for general purulent peritonitis was performed. There was much very offensive pus. The appendix, a large one, was lying to the outer side of the cæcum and presented an extensive gangrenous perforation. There was a large concretion made up of fæcal material in which were five shot (No. 5½ or 6) and a metallic particle. Some of them were marked by contact with the bones of the animal or bird struck (see Fig. 2). The specimens are now in the museum of the Royal College of Surgeons of England. It was stated that this patient was a somewhat hurried eater, also *easily flurried.*

FIG. 2.



Five shot found in a concretion lying in a gangrenous and perforated appendix (From the museum of the Royal College of Surgeons of England.)

Kelly and Hurndon give a reference to a paper by Hevin [9] who says, "A great quantity of shot are sometimes noticed collected in the intestines, especially in the cæcum and appendix, without having caused the slightest inconvenience." One wonders if the subject had undergone the old-fashioned treatment for supposed intussusception. The same authors refer to a case by Holmes, where 122 robin shot were found in the vermiform appendix.

FIG. 3.

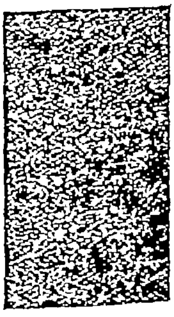


Fig-seeds found in a concretion in an inflamed appendix.

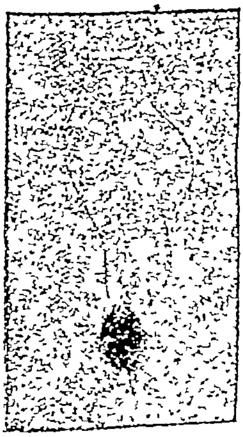
Apple-pips, grape-seeds, and other vegetable substances are apt to find their way past the valve of Gerlach and may be found loose or incorporated in a concretion. The illustration (Fig. 3) (taken from a specimen in the museum of the Royal College of Surgeons of England) is of some fig-seeds which formed part of a concretion, the *history* of which is as follows. The patient was a muscular and active ma aged 35 years, who came under observation in 1906. Ther was a history of a definite attack of appendicitis, wit marked pain in the iliac fossa, but no vomiting, two and a hal years before. He was in the house from 10 to 14 days an found that any attempt to lift the right leg occasioned pai He was unable to do much for six weeks afterwards, an almost ever since had had aching in the appendix region aft exertion. The appendix was 4½ inches long, covered in wit peritoneum, and having an S-shaped curve over the brim the pelvis, up and then down. The tip was buried in th wall of the cæcum. On section there was evidence of forme inflammation and the distal one-third was diminished in si A small concretion was present containing portions of fig seeds. The patient was very fond of figs. The presence of th irregular broken seeds appears to have made the concretio more irritating than is usual.

Hairs are occasionally found forming the nucleus of concretion and may be obtained from many parts of th body. Bitten off ends of the moustache in men, hair fro the *head in females, and so*metimes a bristle from a toot brush. In 1790[10] it is recorded for the first time that a ha was found forming a nucleus to a concretion within th appendix, *and it is interesting* to note the effect produced b such hairs when in that part of the intestinal canal.

FIG. 4.



Hairs caught in a concretion removed *from* a gangrenous appendix which caused fatal peritonitis. (From a specimen in the museum of the Royal College of Surgeons of England.)

In Fig. 4, taken from a specimen (No. 2559 D) in th museum of the Royal College of *Surgeons of England*, th hairs are fine and long. They are mainly two in number an caught by concretions which were in a gangrenous appendi at the time of removal. The *patient* was a little *girl* aged three and a half years, under *my* care in St. Thomas' Hospital, with extensive purulent peritonitis, which proved fatal, in April, 1904. The hairs *evidently* came from the head of the child.

FIG. 5.

Four minute *concretions* with two fine hairs attached, removed from an appendix which appeared healthy *but* had given rise to symptoms of appendicitis. (From the museum of the Royal College of Surgeons of England.)

In Fig. 5 the longer of two hairs was a stiff *bristly* hair, title of Extraordinary Professor.—*Giessen:* Dr. Dannemann, *privat-docent* of Psychiatry, has been promoted to an Extraordinary Professorship.—*Geneva:* Dr. R. de Seigneux, *privat-docent* of Midwifery and Gynæcology, has been promoted to an Extraordinary Professorship.—*Heidelberg:* Dr. Georg Herschel has been recognised as *privat-docent* of Surgery.—*Marburg:* Dr. R. van der Velden has been recognised as *privat-docent* of Anatomy.

---

[10] Encyclopédie Méthodique

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. Ivor Henry Davies, L.R.C.P. & S. Edin., L.F.P.S. Glasg., was entertained at dinner at the Porth Hotel, Porth, Glamorganshire, on July 31st, and was afterwards presented with an address, three silver fruit stands, and a bon-bon dish, as a mark of respect and esteem on the occasion of his leaving Porth.

CLEANLINESS OF THE MILK-SUPPLY IN CARDIFF.—It is gratifying to find that the public generally are beginning to realise that where milk is produced there must be cleanly surroundings. The model regulations under the Dairies, Cowsheds, and Milkshops Order require that, at the time of milking, the udder and teats of a cow shall be thoroughly clean and for neglecting to carry out this regulation a woman was recently fined 40*s.* by the stipendiary magistrate at Cardiff.

THE WEST AFRICAN MEDICAL STAFF.—The promotions of the following officers take effect from the dates given: Mr. W. H. Langley, C.M.G., principal medical officer in the Gold Coast from August 3rd; Mr. J. P. Fagan, deputy principal medical officer in Northern Nigeria from August 3rd; and Dr. St. G. Gray, senior medical officer in Southern Nigeria from April 19th. Dr. M. Cameron Blair, medical officer in Northern Nigeria, is promoted to be senior medical officer in Southern Nigeria from August 3rd. Dr. J. B. Tombleson, medical officer in Southern Nigeria, resigns his appointment on the ground of ill-health from August 7th. The following gentlemen have been appointed to the staff: Mr. P. F. Foran, Southern Nigeria, June 8th; Mr. W. A. Trumper, Northern Nigeria, June 29th; Mr. W. F. Todd, Sierra Leone, August 3rd; Mr. F. O. Hepburn, Southern Nigeria, August 10th; Dr. H. S. Coghill, Southern Nigeria, August 17th; and Mr. T. R. Beale-Browne, Southern Nigeria, August 17th.

THE JAMSETJEE JEEJEEBHOY HOSPITAL NURSING ASSOCIATION.—We learn from an article in the *Times of India* of July 6th that the committee of the Jamsetjee Jeejeebhoy Hospital Nursing Association, Bombay, has just published its report for 1906 and judging by the information supplied in our contemporary the document is evidently an unassuming record of good work performed under exceptional difficulties. In October last 18 members of the nursing staff, or about 20 per cent. of the total number, were simultaneously laid up with typhoid fever. Instead of nursing they had to be nursed, but, thanks to the devotion manifested by the remainder of the staff, the ordinary work of the establishment did not suffer to any great extent. In spite of this mischance the committee is able to announce an important extension in the nursing of the hospital. Several wards which formerly were looked after by native ward-boys and ayahs have now been placed under the supervision of trained nurses. This completes the nursing of the main hospital as well as of the extra Parsi ward. The committee also hopes to be soon able to deal with the eye and out-patients' departments and is drawing up proposals to this end for submission to Government. One of the things it has kept steadily in view is the training of native Indian nurses, Parsi and Hindu, who when fully trained are so much in demand by the general public that they command salaries which their teachers cannot afford to equal. Hitherto one of the chief troubles the committee has had to contend with has been the housing of the probationers, but the "Wadia Home for Nurses" is now approaching completion and will be ready for occupation next May. This home has been well designed and is substantially built, but before it can be used furniture must be procured at a cost of Rs. 15,000. To meet this the Government has granted Rs. 7500; for the balance the committee has to depend on "the philanthropic public of Bombay." No doubt the money will be forthcoming, as well as any additional sums that may be required. The Wadia home will not be able to accommodate the whole of the nursing staff of the Jamsetjee Jeejeebhoy Hospital. At present 28 nurses are living in a house which was acquired for the purposes of hospital extension. When it is razed, as must very soon be the case, accommodation will have to be found elsewhere. It is to be hoped that such devoted sick attendants will not be left homeless.

MEDICAL MAGISTRATE.—The name of Mr. Graham William White, L.D.S.R.C.S. Irel., has been added to the commission of the peace for the borough of Newport (Mon.).

UNIVERSITY COLLEGE, BRISTOL.—A Treasury grant of £4000 has been awarded to University College, Bristol.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Mikhael Radkevich, *privat-docent* of therapeutics in the University of Moscow.—Dr. Frederick R. Weber, professor of medicine in the Milwaukee Medical College.—Dr. Schlagdenhauffen, formerly professor of toxicology and of physics in Nancy.—Dr. Willoughby D. Miller, professor of odontology in the Ann Arbor University, Michigan. He was a medical graduate of Berlin and was well known both in Germany and in America on account of his bacteriological researches in connexion with the mouth and teeth. He also published a work on Conservative Dentistry.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Physical Condition of Glasgow Children.

AN important report made by Dr. W. LESLIE MACKENZIE (medical member of the Local Government Board for Scotland) and Captain A. FOSTER (inspector of physical training) on a collection of statistics as to the physical condition of children attending the public schools of the School Board for Glasgow has been printed as a Parliamentary blue-book. The tables and diagrams on which the report is based have been compiled with the coöperation of the teachers in 73 primary and higher-grade schools in Glasgow grouped in four divisions according to the character of the districts in which they were situated. Returns were made for 72,857 children, of whom 36,883 were boys and 35,974 were girls. Dr. MACKENZIE and Captain FOSTER state that this is the most extensive investigation ever undertaken in Britain as to the heights and weights of school children in primary and higher-grade schools. The tables and diagrams may legitimately be held to be a provisional standard for future investigations.

The Public Health Bill.

A committee of the House of Lords, including the Duke of NORTHUMBERLAND, the Earl of ONSLOW, the Earl of DONOUGHMORE, Lord FITZMAURICE, and Lord ALLENDALE has been appointed to examine the clauses of the Public Health Bill.

HOUSE OF LORDS.

THURSDAY, AUGUST 8TH.

The Vaccination Bill.

THE House went into committee on the Vaccination Bill.

Lord BALFOUR of BURLEIGH moved an amendment to the effect that the obligation of making the statutory declaration required by the Bill in order to obtain exemption should in the first instance rest upon the father of the child. He pointed out that the amendment would restore the Bill to the form it was in when it was originally introduced. An amendment extending the right of making a statutory declaration of objection to each parent was subsequently introduced in the Standing Committee of the House of Commons, but on that occasion it was strongly opposed by Mr Burns and Dr. Macnamara, the representatives of the Local Government Board.

The Earl of CREWE resisted Lord Balfour's amendment. The fact that either parent might make the statutory declaration would conduce to the convenience of parties availing themselves of the Bill.

On a division the amendment was carried by 30 votes to 25.

The Bill was reported to the House.

Butter and Margarine Bill.

The House also considered the Butter and Margarine Bill in Committee.

Earl CARRINGTON moved a new clause to give the Local Government Board power after inquiry to make regulations to prohibit the use of preservatives which they thought undesirable or to limit their use in the preparation and sale of butter, margarine, or milk-blended butter.

The new clause was agreed to.

The Bill was ultimately reported to the House.

Stabb, to explore the chest by costo-chondral resection. About two inches of the second and third left rib-cartilages were resected and the patient, at the time I write, now reclines comfortably, and avers she can both breathe and swallow more easily, and does so.

One might legitimately, therefore, surmise *a priori* that when the central organ takes the initiative in congesting and encroaching upon the lungs, relief of intrathoracic pressure by costal resection might also in some cases be beneficial. This view, if you remember, was that which I put forward in a paper on "Pericarditis in Childhood" which I read before this society last year and which was later published in THE LANCET.[1] It is, indeed, a view which I have advocated for several years, but without convincing others, possibly because I have not boldy put it into practice. The same timidity, however, has not been exhibited in Germany, where Brauer, of whose work I was until recently unaware, has successfully treated several cases of adherent pericardium by causing surgeons to remove a sufficient amount of costo-chondral surface in the præcordia, and his example has been followed in Holland by Wenckebach in one case. I cannot now give the details of these cases, but it will suffice to relate (1) that the operation was not difficult, as one would expect; and (2) that the general effect in improving the action of the heart and in promoting an easier circulation was obtained by the procedure. All these cases were diagnosed as adherent pericardium, although the sac was not opened, and in some of them costo-pericardial adhesion under the surface removed was not found. The pericardial tethering was, therefore, assumed to be elsewhere, that is, pleuro-pericardial. This fact also, however, has interest, for the question arises whether mere cardiac bulk is not a disadvantage in these circumstances and whether, therefore, the justification does not arise for attempting to relieve pressure by the removal of a portion of the ribs and cartilages in the præcordia, in obedience to the indications given by the præcordial bulging of children, even when it may be assumed that actual pericardial tethering is absent. I think personally, we shall soon be justified in this matter in following John Hunter's advice to Jenner when the latter was too timid to vaccinate but thought he might do so with safety. "Why think?" said Hunter; "do it." I believe we shall also in this matter be able to "do it" with safety and with benefit, both to patients and to our own reputation.

PANCREATITIS DUE TO DIRECT EXTENSION OF A MALIGNANT GROWTH OF THE GALL-BLADDER ALONG THE COMMON BILE AND PANCREATIC DUCTS.

BY A. W. MAYO ROBSON, D.SC., F.R.C.S. ENG.,
HONORARY SURGEON TO THE DREADNOUGHT HOSPITAL;

AND

P. J. CAMMIDGE, M.B. LOND., D.P.H. CANTAB.

THE following case appears to us to be of sufficient interest, both from a clinical and pathological point of view, to make it worthy of being reported.

The patient, a man, aged 61 years, was seen by one of us in consultation with Dr. Carter on the evening of March 2nd, 1907. He was extremely ill and it appeared clear to both his medical attendants and his friends that unless something could be done to relieve him he had not long to live. He gave the history that he had been perfectly well up to 13 months previously, when he began to have some abdominal pain on the right side beneath the costal margin. Although he was able to go to business, he had to leave off work from time to time on account of more severe seizures of pain, the attacks resembling, and, in fact, being diagnosed as, gall stone seizures. From the time of his first attack of pain he began to lose flesh and in November, 1906, after a more severe attack than usual, jaundice supervened, but it cleared up in a fortnight. Three weeks before being seen he had had another severe attack followed by jaundice, which, however, had now subsided. With the jaundice the abdomen became swollen and very tender on the right side. For one week he had had some fever of an irregular type, associated with occasional shivering attacks and vomiting. At the time of the consultation he was markedly emaciated and very feeble, the abdomen was distended, but no fluid thrill could be felt. There was great tenderness on the right side of the abdomen, apparently due to local peritonitis, so that it was impossible accurately to palpate the region; nevertheless, gentle pressure revealed a distinct swelling which reached below the level of the umbilicus. It was hard, distinct, tender, and rounded and was apparently a distended gall-bladder. Above this swelling could be felt a hard nodule at the edge of the liver. The skin was deeply jaundiced, the urine was dark, and the fæces were pale. There was no œdema of the legs and no evidence of ascites could be found. Immediately after the abdomen had been examined the patient had a shivering attack and the temperature went up at once to 104° F. A diagnosis was made of suppuration in the gall-bladder, possibly associated with gall-stones and probably with malignant disease. An exploratory operation was recommended, and, although it was thought that the patient would be too ill to bear any extensive operative procedure, it was hoped that pus might be evacuated and so give relief.

Analyses of specimens of urine, fæces, and stomach contents were made on March 3rd with the following results.

Urine.—Reaction, acid; specific gravity, 1·020; albumin, *nil*; sugar, *nil*; acetone, *nil*; diacetic acid, *nil*; indican, *nil*; bile, a well-marked reaction; urobilin, *nil*; urea, 2·7 per cent.; chlorides, 0 4 per cent.; phosphates, 0 3 per cent.; microscopically, squamous and transitional epithelium; "pancreatic" reaction (C), many fine crystals, soluble in 33 per cent. sulphuric acid in ten seconds (Fig. 1).

Fæces.—Appearance, soft, grey-brown, solid; reaction, alkaline; stercobilin, traces; microscopically, many fat globules, a few fatty acid and soap crystals, some undigested muscle fibre; organic matter, 91·5 per cent. of the dry weight; "total fat," 39·6 per cent.; "neutral fat," 31·8 per cent.; "combined fatty acid," 7·8 per cent.; organic matter, not fat, 51·9 per cent.; inorganic ash, 8·5 per cent.

Stomach contents.—Reaction to litmus, acid; congo-red reaction, deep blue; phloroglucin vanillin reaction, pink; lactic acid, traces; albumin, a well-marked reaction; albumoses and peptone, a well-marked reaction; mucus, a large amount; dextrin, a well-marked reaction; sugar, *nil*; blood, *nil*; bile, *nil*; microscopically, much glairy mucus, many fat globules, some starch granules, many sarcinæ, some yeast cells, a few bacilli. Quantitative examination: total acid, 0·12 per cent.; total chlorides, 0·32 per cent.; inorganic chlorides, 0 22 per cent.; physiologically active hydrochloric acid, 0·10 per cent.

The conclusions drawn from the above results were stated as follows:—

> The large amount of bile pigment in this specimen of urine shows that there is some serious obstruction to the free flow of bile into the intestine. The positive result of the "C pancreatic" reaction points to there being active degenerative changes in the pancreas, probably of an inflammatory nature, and suggests that the cause of the obstruction to the bile flow is also interfering with the functions of the pancreas. The character of the pancreatic reaction, the presence of traces of stercobilin in the fæces, the normal proportion of physiologically active hydrochloric acid, and the presence of free hydrochloric acid in the vomit are against the obstruction being due to malignant disease of the head of the pancreas and suggest a diagnosis of impacted gall-stones in the common bile duct. The excess of unabsorbed fat in the fæces, together with the fact that this excess is entirely due to "neutral fat" tends to confirm the diagnosis of there being some interference with the functions of the pancreas. The excess of fat is, however, not so marked as is usually seen in malignant disease of the head of the gland and points to the defective digestion being due to an inflammatory lesion of the pancreas The results of the analysis of the stomach contents are against a diagnosis of primary malignant disease of the pancreas or stomach, but the microscopical characters and the presence of lactic acid suggest that there is probably some stagnation of the stomach contents.

The pathological analyses therefore pointed to there being a considerable degree of pancreatic inflammation associated with, and secondary to, obstruction of the common bile-duct and since the evidence available did not favour this being due to a malignant growth of the head of the pancreas it was inferred that it arose from the most common cause—namely, an impacted biliary calculus in the pancreatic portion of the common bile-duct. The presence of free hydrochloric acid and the normal proportion of physiologically active acid found in the stomach contents also tended, according to the investigation of Moore and his fellow-workers, to contraindicate a diagnosis of cancer elsewhere and favoured the opinion that the

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Ash, Edwin L., M.B. Lond., M.R.C.S. Eng., has been appointed Clinical Assistant at the Great Northern Central Hospital, London.

Battersby, James, F.R.C.S. Eng., has been appointed Lecturer on Anatomy in St. Mungo's College, Glasgow.

Danvers, H., M.D Parma, L.R.C P. & S. Edin., L.F.P.S. Glasg., has been appointed Assistant Physician to the Italian Hospital, Queen-square, W.C.

Ellison, Francis Charles, M D. Dub., has been appointed Resident Medical Superintendent at the Mayo County Asylum, Castlebar.

Knox, Robert, M.D. Edin., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer in charge of the Electrical Department at the Great Northern Central Hospital.

Muir, Gavin D., M.B., Ch.B. Glasg., has been appointed Resident Medical Officer at the Royal Albert Hospital, Devonport.

Penny, Sydney Greenwood, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Fourth District by the Penzance Board of Guardians.

Thomas, J. H., L.R.C.P. Edin., M.R.C.S. Eng., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Market Harborough District of the county of Leicester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Aberdeen Provincial Committee for the Training of Teachers.—Lecturer on Hygiene. Salary £400.

Birmingham and Midland Hospital for Skin and Urinary Diseases.—Clinical Assistant. Salary at rate of 52 guineas per annum.

Birmingham General Hospital.—Three Receiving-room Officers. Salary £150 per annum.

Birmingham, Queen's Hospital.—House Physician. Also Obstetric and Ophthalmic House Surgeon for seven months. Salaries at the rate of £50 per annum, with board, lodging, and washing.

Bombay Municipality.—Two Assistant Health Officers. Salaries Rs. 750, rising to Rs. 1000, and Rs. 600, rising to Rs. 750 per mensem respectively.

Bradford Sanatorium for Consumptives, Eastby, near Skipton.—Resident Medical Officer. Salary £100, with rations, apartments, and washing.

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary £100 per annum, with board and lodgings.

Bristol Royal Infirmary.—Resident Junior House Surgeon; also Resident Casualty Officer, each for six months. Salaries at rate of £50 per annum, with board, lodging, and washing.

Bury Infirmary.—Junior House Surgeon. Salary £80, increasing to £90, with board, residence, and attendance.

Buxton, Devonshire Hospital.—Assistant House Surgeon for six months. Salary £70 per annum, with apartments, board, and laundry.

Cairo, School of Medicine (Egyptian Government, Ministry of Education).—Assistant to the Professor of Pathology. Salary £E. 320 per annum.

Derby County Asylum, Mickleover.—Junior Assistant Medical Officer. Salary £120, rising to £150 per annum, with apartments, board, washing, and attendance.

Devon County Asylum.—Assistant Medical Officer. Salary £140, with board, apartments, and laundry.

Dover, Royal Victoria Hospital.—House Surgeon, unmarried. Salary £100 a year, with board, lodging, and washing.

Dublin, Royal Victoria Eye and Ear Hospital, Adelaide-road.—House Surgeon. Salary £40, with board and residence.

Dudley, Guest Hospital.—Assistant House Surgeon for six months. Salary £80 per annum, with residence, board, and washing.

Dumfries and Galloway Royal Infirmary.—Assistant House Surgeon. Salary £40 per annum, with board and washing.

Egyptian Government, Kasr-el-Ainy Hospital.—Resident Medical Officer. Pay £250 a year, with quarters, servants, washing, coals, and light.

Epping Union.—District Medical Officers and Public Vaccinators for Parndon District, for the Parish of Roydon, and for the Parish of Nazeing. Salaries £32, £30, and £40 per annum, and fees.

Glasgow District Asylum, Woodilee, Lenzie.—Assistant Medical Officer. Salary £135 per annum, with board, lodging, &c.

Huddersfield Infirmary.—Junior House Surgeon. Salary £80 per annum, with board, residence, and washing.

Hull, Royal Infirmary.—Casualty House Surgeon. Salary £50, with board and lodging.

Kensington General Hospital, Earl's Court, London, S.W.—Senior and Junior Resident Medical Officer. Salary £60 and £40 per annum respectively, with board, washing, and residence.

Lowestoft Hospital.—House Surgeon, unmarried, for six months. Salary at rate of £80 per annum, with board, lodgings, and washing.

Loughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary £100 a year, with rooms, attendance, board, and washing.

Manchester, Ancoats Hospital.—Resident House Physician. Salary £80 per annum, with board, residence, &c.

Manchester Workhouse, Crumpsall.—Assistant Medical Officer. Salary £110 per annum, with apartments, fire, light, washing, and attendance.

Northampton General Hospital.—Assistant House Surgeon. Salary £50 a year, with apartments, board, washing, and attendance.

Orkney, Parish of Rousay and Egilshay.—Resident Medical Officer. Salary £51 per annum.

Pendleton, Salford Union Infirmary, Hope.—Resident Medical Officer. Salary £130 per annum, with apartments and attendance.

Prestwich, Manchester, County Asylum.—Junior Assistant Medical Officer, unmarried. Salary £150, increasing to £250, with board, apartments, and washing.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 a year, with board, lodging, and washing.

Southport Infirmary.—Resident Senior House Surgeon, unmarried, for six months. Salary at rate of £90 per annum, with residence, board, and washing.

Stockport Infirmary.—Junior Assistant House Surgeon for six months. Salary £40 per annum, with board, washing, and residence.

Stoke-on-Trent, North Staffordshire Infirmary and Eye Hospital, Hartshill.—Junior House Surgeon. Salary £80 per annum, with board, apartments, and washing.

Surrey, London County Asylum, Long Grove, Epsom.—Assistant Medical Officer. Salary £160 a year, with board, apartments, and washing.

Taunton and Somerset Hospital, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

West London Hospital, Hammersmith-road, W.—Two House Physicians and Three House Surgeons, tenable for six months.

Worcester County and City Asylum.—Assistant Medical Officer, unmarried. Salary £140, rising to £160, all found.

York County Hospital.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

York Dispensary.—Two Resident Medical Officers, unmarried. Salaries £120 per annum, with board, lodging, and attendance.

The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Strathmiglo, in the county of Fife.

Births, Marriages, and Deaths.

BIRTHS.

Cooke.—On August 7th, at Fairholm, Walsall, the wife of John G. Cooke, M.B. Cantab., of a son.

Cooper.—On August 6th, at Great Portland-street, W., the wife of A. Tanner Cooper, M.R.C.S., L.R.C.P., of a son.

Evanson-Jones.—On August 8th, at Ashton Old-road, Manchester, the wife of E. Evanson-Jones, L.R.C.P. & S. Edin., L.F.P.S. Glasg., of a son.

Harman.—On August 10th, at Harley-street, W., the wife of N. Bishop Harman, F.R.C S., of a son.

Hatrick.—On August 11th, at Welland House, New Barnet, Herts, the wife of Charles D. Hatrick, M.D., of twin daughters.

Key.—On August 12th, at Valetta, Clarendon-road, Southsea, the wife of M. Aston Key, M.B., B.C. Camb., of a daughter.

Smith.—On August 11th, at Walden House, Watford, the wife of G. Francis Smith, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

MARRIAGE.

Millard—Foster.—On June 26th, at Aliwal North, Cape Colony, Philip E. Millard, M.D., to Edith Ursula, daughter of the late W. H. Foster, Esq.

DEATHS.

Brown.—On August 12th, aged 50 years, Walter Henry Brown, M.Sc. Leeds, F.R.C.S. Irel., M.R.C.S. Eng., of Highfield House, Headingley, Leeds.

Morison.—At 8, Ross-road, Wallington, Surrey, on August 13th, in her eighty-second year, Margaret Gordon Maclellan, widow of Alexander Cushnie Morison, Esq., Surgeon in the Military Service of the Honourable East India Company.

Williams.—On August 11th, at 48, Prince of Wales-road, Norwich, Charles Williams, F.R.C.S.E.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

During the week marked copies of the following newspapers have been received:—*Gloucestershire Echo, Stowmarket Weekly Post, Daily Graphic, Daily News, Standard, Sussex News, Tribune, Daily Telegraph, Morning Post, Hereford Times, Yorkshire Daily Observer, Newcastle Daily Chronicle, Bombay Gazette, Edinburgh Evening Dispatch, Fife Herald, Justice, Black and White, Nottingham Evening News, Rand Daily Mail, Newcastle Chronicle, Free Lance, &c.*

obstruction was of a simple nature, but as in two other cases of growth blocking the common bile-duct high up we had found both free hydrochloric acid and a normal proportion of physiologically active acid in the material regained from the stomach after a test meal we did not lay much stress on this point. In both of these cases, however, we had failed to find any trace of stercobilin in the fæces, and there was not only a very large excess of "neutral fat" but the fæces also contained a high proportion of "combined fatty acid," so that the presence of stercobilin in this instance, together with the other results of the chemical examination of the fæces, inclined us to take the view that the obstruction was probably due to gall-stones. The only point not readily explained on this hypothesis was the evident stagnation of the stomach contents, but it was assumed that this was due to dilatation of the stomach from some independent cause.

The patient was removed to a nursing home, and on March 4th an exploratory operation was performed, a vertical incision being made over the centre of the tumour. Pus was soon reached and it was found that the abscess walls were composed of broken-down growth. A drainage-tube was inserted and the wound was closed as it was quite clear that nothing further could be done. The patient was temporarily relieved by the evacuation of the pus, but his pulse, which was very feeble before the operation, in a few hours became very rapid, and he only survived until the following day.

A partial post-mortem examination was made 18 hours after death, permission only being given for an examination to be made through the operation wound. The drainage-tube was found to lead into an irregular cavity, lined with soft friable material, which occupied the position of the gall-bladder, no trace of which could be found. The growth was intimately adherent to the pylorus, first part of the duodenum, and colon, so the stomach, duodenum, colon, liver, and pancreas were removed *en masse* for more detailed investigation. Dissection showed that the walls of the cavity varied from three-quarters of an inch to one inch in thickness, except anteriorly, where they consisted of a thin layer of inflammatory exudate. Above and behind it was bounded by the liver, while below it was adherent to the colon and pyloric extremity of the stomach. The line of demarcation between the liver substance and the growth was somewhat irregular but could be easily traced. No metastatic growths could be discovered in the liver. An examination of the interior of the stomach and intestine showed that the walls of the pyloric canal and the first two inches of the duodenum were adherent to, and invaded by, the growth. In several places fungating masses protruded into the lumen of the stomach and duodenum, but no penetration of the walls of the colon had taken place. The common bile-duct could be traced through the head of the pancreas and along the left margin of the growth to its upper extremity, where it was lost as a distinct canal, although the presence of bile-stained material indicated the direction in which it passed. The duct was found to be dilated and filled with soft, bile-stained material throughout its length. The head of the pancreas did not appear to be invaded by the growth and could be easily and cleanly separated from it. The pancreas, and especially the head of the gland, was larger and harder than normal. On section no evidence of any secondary deposits could be detected by the naked eye. On dissecting out the duct of Wirsung it was found to be dilated and to be filled with bile-stained débris, similar to that seen in the common bile-duct, for one and a half inches from its duodenal opening; beyond that it was filled with white opaque material free from any trace of bile.

Histological examination.—Preparations made from the walls of the cavity in the liver showed masses of columnar cells, arranged in more or less regular columns and alveoli separated by delicate strands of fibrous tissue (Fig. 2) Sections of the common bile-duct showed that its lumen was occupied by masses of columnar cells and amorphous débris. Many of the cells were deeply stained with bile. In some places continuous strands of five or six cells could be seen. The walls of the duct were thickened and infiltrated with patches of small round cells. In places irregular masses of columnar cells could be seen penetrating the walls (Fig. 3). Sections of the duct of Wirsung and adjacent tissue in the head of the pancreas showed that the lumen of the duct was filled with bile-stained columnar cells and débris similar to that found in the common bile-duct. The walls of the duct were irregular and much thickened. Patches of columnar cells were found in the fibrous tissue of the walls and lying in the fibrous strands separating the neighbouring pancreatic lobules (Fig. 4). Preparations made from the head of the pancreas in various situations showed well-marked interstitial pancreatitis of the interlobular type, the lobules being separated by wide strands of fibrous tissue, which in places invaded the periphery of the lobules. Scattered in the interlobular tissue were small irregular patches of columnar cells, some of which occurred as solid masses, while others were grouped about a more or less distinct lumen. The latter, however, could be readily distinguished from the normal interlobular ducts by the atypical arrangement of the cells and the absence of any limiting membrane or duct wall. No direct invasion of the head of the pancreas by the growth appeared to have occurred and the patches of growth were most numerous in the neighbourhood of the duct of Wirsung (Figs. 5 and 6). Sections of the body and tail of the pancreas showed no marked overgrowth of interstitial tissue but the cells of the parenchyma were swollen and granular, having the histological characters seen in cloudy swelling.

The post-mortem examination thus proved that the cavity opened at operation was due to a columnar-celled carcinoma of the gall-bladder which had invaded the stomach and first part of the duodenum and was adherent to the colon. The obstruction of the pylorus caused by the growth accounted for the vomiting that occurred during life, and also explained the evidences of stagnation of the stomach contents found in the pathological examination. The destruction of the upper part of the common bile-duct, and the presence of a mass of disintegrated growth in its remaining section, were undoubtedly the cause of the jaundice, but the bile-stained character of the cells in the lumen of the duct and the presence of stercobilin in the fæces showed that some bile was able to find its way along the duct into the intestine, the obstruction thus not being absolute as it is in most cases of primary cancer of the head of the pancreas.

The most interesting feature of the case is the condition of the pancreas and the duct of Wirsung. The latter was filled with débris similar to that found in the common bile-duct, and as the part of the pancreatic duct nearest to this was stained with bile it was evident that not only had masses of cells passed from the common duct into the duct of Wirsung but that a certain amount of bile had also followed the same course. According to Opie the passage of bile into the pancreatic duct is a cause of acute pancreatitis, and although there were well-marked evidences of inflammatory changes these were not of the acute type, and during life there had been none of the symptoms usually associated with acute pancreatitis. Recent experiments by Flexner have tended to show that the active constituent of bile giving rise to inflammation of the pancreas is the bile salts, and that when these are modified by prolonged stay in the ducts or diluted with colloid material they cause chronic inflammation and not an acute fulminating lesion. This is probably, in part, the explanation of the pancreatitis found in the case under consideration. But in addition we have also to take into account the obstruction to the free outflow of the pancreatic secretion caused by the blocking of the ducts and the irritation of the gland by deposits of growth within its substance. The much more advanced stage of the lesion found in the head of the gland is possibly to be explained by its earlier invasion by the growth and its more direct contact with the bile passing from the common bile-duct into the duct of Wirsung, but it has also to be borne in mind that malignant disease of the gall-bladder very frequently follows irritation by gall-stones and that chronic pancreatitis is also most commonly the result of the passage of biliary calculi along the common duct. The fact that there was advanced fibrosis of the head, while the body and tail only showed the characters of catarrhal pancreatitis, with no marked increase of fibrous tissue, lends support to the view that the affection of the head of the gland was of much earlier date than the disease of the body and tail of the organ.

The absence of any direct connexion, either macroscopically or microscopically, of the growth with the pancreas, the more numerous deposits of growth in the neighbourhood of the duct of Wirsung, and the absence of deposits elsewhere suggest that the involvement of the pancreas was by way of the common bile and pancreatic ducts. So far as we are aware this direct method of extension has not as yet been described and is a cause of pancreatitis of which we have no previous knowledge. It was no doubt rendered possible by the soft friable character of the growth, but as

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1907, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid *to* London or *to* local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch" should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

A CASE OF APPENDICITIS EXCITED BY A CLOVE, THE APPENDIX BEING THE SOLE VISCUS IN A HERNIAL SAC.

By W. HAL BARNETT, M.B., B.S. LOND.,

AND

J. W. SCOTT MACFIE, B.A., B.SC., M.B., B.CH. EDIN.,

HOUSE SURGEONS TO THE RADCLIFFE INFIRMARY AND COUNTY HOSPITAL, OXFORD.

THE patient who is the subject of this note was a man 58 years of age, who was admitted to the Radcliffe Infirmary and County Hospital on May 5th, 1907, complaining of a tense and painful swelling in his right groin. The history of the case was as follows. For quite 20 years the patient had suffered from a rupture in the right inguinal region, which he controlled by the use of a truss during the day-time. He was never inconvenienced by this and when, as occasionally happened, the bowel came down he was easily able to return it. One morning, however, about a week before his admission, he awoke to find that a swelling had come down, which, unlike his usual rupture, was hard and painful. He thought, however, that it must be the rupture and tried to reduce it as usual. This he was unable to do, but he nevertheless applied his truss on top of it and went about his daily work. At first the swelling, though painful, did not cause him any considerable inconvenience, but after a day or two he noticed that it was rapidly growing larger and at the same time the aching pain "as though something were gripping him hard" became so severe that he was unable to get about at all. On the next night (May 4th) he called in a medical man who, after attempting reduction without success, advised the patient to come to the Radcliffe Infirmary as soon as possible.

On admission the patient appeared to be somewhat anæmic. He was a man of a rather unhealthy appearance. His tongue was dry and clean and it was noticed that the lower parts of his abdomen and his thighs were deeply pigmented. Vomiting had not occurred and his bowels had been moved regularly throughout his illness. His temperature was 99° F. On inspecting the right inguinal region a considerable amount of swelling was observed running down into the scrotum, the skin overlying it was healthy, and no visible impulse was detected on coughing. On palpating the tumour it was found to be very hard, elongated and oval in shape, and about three inches by one inch in size. Its surface was smooth and the mass could be traced from the internal ring down the canal as far as the testicle. It was exquisitely tender to the touch. Percussion only showed that the swelling produced a dull note and nothing could be made out by rectal examination. On May 6th Mr. R. H. A. Whitelocke exposed the tumour by an incision made over the swelling. A small quantity of clear straw-coloured fluid exuded on pricking the sac, and on further opening the mass a rough-walled cavity was laid bare containing a dark red elongated mass. Some purulent material was found, and on lifting up the red mass a clove was discovered lying beneath it. It was then realised that the tumour consisted of a short but very greatly thickened appendix lying in a hernial sac, and accordingly it was removed and the stump cauterised with pure carbolic acid and buried. No other viscus was found to be present in the sac.

It is curious and interesting to note that the patient affirmed that he had not tasted cloves in his food for some time, the last occasion being about a month before his admission, when he remembered having cloves in an apple pudding. Nevertheless, the clove, when removed, was found to be well preserved, the antiseptic action of its essential oils having probably protected it from decomposition. It was in every respect complete, with the exception of one division of the calyx, which was knocked off during the operation, and a little soft and swollen as might have been expected.

We have to express our thanks to Mr. Whitelocke for permission to publish the notes of this case, which appears to be of interest, first, because of the difficulty of diagnosis, for the tumour felt almost like a malignant mass, and yet it had come down so suddenly; secondly, because of the unusual cause—a clove; and thirdly, in that the appendix, greatly thickened and inflamed, was the sole viscus in the sac.

A RECORD OF THE PHYSICAL EXAMINATION OF 1000 BOYS AT THEIR ENTRANCE ON PUBLIC SCHOOL LIFE.[1]

By CLEMENT DUKES, M.D., B.S. LOND., F.R.C.P. LOND., J.P.,

PHYSICIAN TO RUGBY SCHOOL.

BY the courtesy of the headmaster of Rugby School I am permitted to submit to the International Congress of School Hygiene the results of the physical examination of 1000 boys on admission to a public school between the ages of 13 and 15 years. These British boys may be regarded as a special class: strong and healthy, well-bred, well-fed, and reared mainly in the country. For even where in some instances their infancy and childhood were passed in towns and cities, the period of life from the age of 9 to 13 years was usually spent in the country at admirable preparatory schools. The record is entirely free from selection The examinations were made as the boys severally entered the school and were solely intended to serve as a basis for regulating each boy's physical welfare during his secondary school life by detailing minutely his exact physical state and thereby affording a sure guide to the masters in the appropriate course of education, and for determining the physical exercise and games suitable to each boy's constitution and vigour.

Prior to registering the result of the examinations I drew up a schedule for recording the proposed analysis of my observations and submitted it to the Editor of THE LANCET with a request that he would refer the form to experts for suggestions tending to its completeness for its purpose. He replied:—"I have submitted your Physical Examination Chart to the author of the leading article in THE LANCET and to one other gentleman taking particular interest in anthropometry. Neither has any suggestion to make. They consider the chart to cover the ground entirely." I insert a copy of the scheme:—

N = Normal. *Private and Confidential.*

[1] A paper read before the Second International Congress of School Hygiene, held at the University of London, August 5th-10th, 1907.

A Lecture

ON

THE PRINCIPLES OF VACCINE-THERAPY.

Delivered before the Harvey Society of New York

By Sir A. E. WRIGHT, M.D. Dub., F.R.S.,

SOMETIME PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY; DIRECTOR IN MEDICAL CHARGE OF THE DEPARTMENT FOR THERAPEUTIC INOCULATION, ST. MARY'S HOSPITAL, LONDON, W.

(Concluded from p. 427.)

We have next to make a detailed study of the curves of immunisation which are obtained by the inoculation of bacterial vaccines and to make acquaintance with the laws which govern the output into the blood of the opsonins and other bacteriotropic substances which are produced in the organism in response to an *ictus immunisatorius*.

Detailed Study of the Curves of Immunisation which are Obtained by the Inoculation of Bacterial Vaccines.

Such a record as is furnished by the immunisation chart reproduced in Fig. 1 gives an inadequate, and, be it noted, a quite fallaciously inadequate, account of the events which occur in the blood after the inoculation of bacterial vaccines.

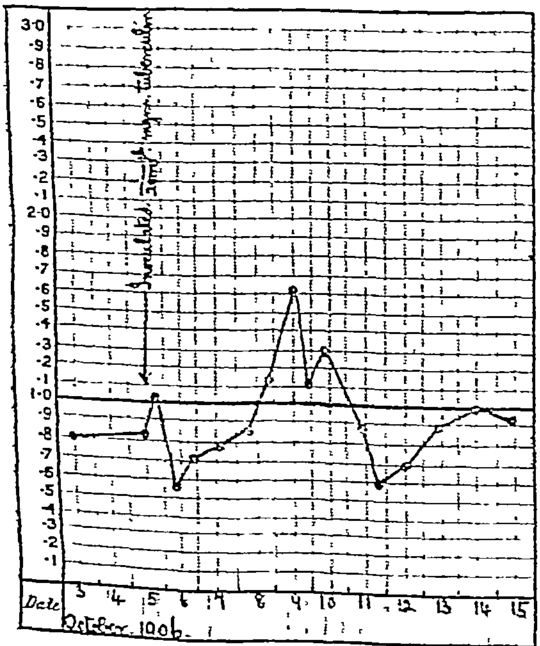

Fig. 2.

Curve showing the changes in the opsonic power of the blood which followed upon the inoculation of $\frac{1}{1000}$ milligramme of tuberculin into a patient suffering from tuberculous cystitis.

When, instead of testing the blood after inoculation at intervals of from a week to ten days, as was done in the case of the patient whose immunisation chart has just been considered, the blood is tested from day to day, it is borne in upon us that the augmentation of the bacteriotropic power—or, let us rather phrase it, the rise in the bacteriotropic pressure—of the blood is generally preceded by a depression. It is borne in upon us also that the rise which is achieved by inoculation is only a transient rise, and that the bacteriotropic pressure generally declines after the interval of a few days, sometimes sinking away until it reaches the point at which it started, in other cases running along for a time at a level only a little above the original base line. I have spoken of the sinking away of the bacteriotropic pressure as the "negative phase" and of the rise of pressure as the "positive phase" of the reaction of immunity. And I have tried to delineate in words the whole oscillation by speaking of "the ebb" (the *negative phase*), "the flow" (*positive phase*), "the backflow" (subsequent decline of the curve), and the "sustained high tide of immunity."

This phrase describes only the larger features of the curve. Where more frequent and in particular where earlier blood examinations are made another practically constant feature reveals itself. This is the transient initial rise preceding the negative phase. We may think of this as of a wavelet which arrives before the ebb which precedes the main wave of immunity. This wavelet and its position in the general scheme of oscillation is shown on the record below. (Fig. 2.)

It is not to be assumed that the form of curve, as set forth in the chart above, is universally conformed to. Where a dose of vaccine which is only just sufficient to produce a result is administered the negative phase is elided and there is registered only a positive phase. The curve in such a case neither rises so high nor does it maintain itself so long above the base line, as in the case where a larger quantum of vaccine has been administered.

Where an excessive dose of vaccine is administered—meaning here by an excessive dose a dose whose inoculation produces severe constitutional symptoms—the negative phase is proportionately accentuated and prolonged. Where the quantum of vaccine is immoderately large the bacteriotropic blood pressure may be reduced for a period of weeks. The advent of a positive phase may often in such a case be awaited in vain.[1]

Chronology of the different phases of the curve of immunisation.—Having now learned the features of the curves which are obtained after the inoculation of different quanta of bacterial vaccines we may further study the chronology of the successive incidents. The traditional view—a view which would seem to have been derived from experience with vaccinia—is that a period of ten days is always required for the establishment of active immunity. Largely owing to the fact that this view was adopted by Pasteur, it became part of the routine religion of bacteriologists, animals and men being subjected to test inoculations or to reinoculation on the expiration of a fixed period of ten days. So far as I know Haffkine was the first to claim that a condition of immunity was achieved already within 24 hours after the inoculation of a vaccine. He put forward this claim in connexion with his plague vaccine, basing his contention on the statistical results of anti-plague inoculations undertaken respectively in the Byculla Gaol in Bombay and in the village of Undhera. Some years afterwards, the matter having in the meantime been advanced a step further by the publication, under Haffkine's auspices, of evidence pointing to the successful inoculation of patients who were already in the incubation period of plague—I obtained in the course of a study of the changes effected by antityphoid inoculation in the bactericidal power of the blood evidence of development of increased bactericidal power in the blood on the day subsequent to the inoculation of moderate doses of antityphoid vaccine. Following upon that I obtained in connexion with my first therapeutic inoculations of staphylococcus vaccine evidence of increased phagocytic response on the day subsequent to inoculation. One would have thought that the achievement of an immunising effect within so short a period as 24 hours would have constituted a record. We have, however, during the last 12 months obtained in very numerous cases conclusive evidence of an augmentation of the opsonic power of the blood within an hour after the inoculation of tubercle vaccine, and also trustworthy witness of associated clinical improvement within that time in connexion with the inoculation of tubercle vaccine in an infection of the eye. We have also, in connexion with the treatment of furunculosis by inoculations of staphylococcus at the hands of the drill-sergeant or the gymnasium instructor.

---

[1] It may be interesting in this connexion to note the following points. 1. Immoderate negative phases due to over-dosage rarely come under observation except in the case of patients who are new to inoculations. After a prolonged series of inoculations it is the rule (but by no means an invariable rule) to find that a large surplus of vaccine over that which is required to raise the bacteriotropic pressure of the blood can be tolerated. 2. Where by inadvertence an excessive dose of vaccine has been administered it is unnecessary indefinitely to await the return of the bacteriotropic pressure to the normal. In such a case the desired rise can practically always be obtained by reinoculating, as soon as all constitutional symptoms have disappeared, with a minimal dose of vaccine. 3. The initial rise which has been referred to in the text may come into observation also in connexion with the inoculation of an immoderate dose of vaccine. It may therefore be provisionally assumed that such initial rise is the response of the organism to the fraction of the total dose which is immediately absorbed.

It is somewhat depressing to register in the twentieth century the large number of acquired preventable deformities (not momentous, it is true, but still indicative of inferior systems of nurture and education) which are presented by the most favoured class of boys in Great Britain—deformities occurring between the time of nursery-life and the completion of education in the preparatory school at the age of 13 Some of these infirmities arise from faults in nutrition during infancy, which entail rickets. And these defects in nutrition, as a cause, tend at the present day to involve the children of the rich even more than those of the poor in their sequent physical evils. For a preponderating proportion of mothers in the higher social rank either cannot, or will not, nurse their children; and more than this, substitute for the naturally-appointed breast-milk, boiled cows' milk, which, in the process of boiling, is deprived of some element in its nutritive value which tends to the advent of rickets or infantile scurvy. Also resort is made to various artificial foods, equally insufficient for the adequate nourishment of infants in their earliest months of life. On the other hand, some of these deformities may result from the debilitating effects of infantile maladies, while the remainder are incidental to unnatural school methods and the disfiguring effect produced by faulty postures, permitted or practically compelled during school-life, so that the supple bones become moulded imperceptibly, but surely, into abnormal forms.

Congenital deformities	Malformation of the ear	2
	Malformation of the little toe ...	1
	Hammer toes	5
	Undescended testicles	9
Acquired deformities	Antero-posterior curvature of spine	1
	Lateral curvature of spine... ...	445

Urinary System.

The number of instances of albuminuria is somewhat startling to those who have not devoted special attention to the subject at early ages; but this functional disturbance is not of serious importance. Amongst those who were known to have this ailment during school life I have never once found the condition existent when they had arrived at maturity. While the malady is largely dependent upon the state of the vaso-motor system, it is also subject to some condition of the blood, inasmuch as Sir A. E. Wright has shown incontestably that it is at once removed by supplying the blood with lime salts either in the form of an abundance of milk (which contains a large amount of lime) or by the administration of lactate of lime. In the interests of the growth, development, and happiness of boys at school, therefore, I would once again urge the importance of not placing lads exhibiting this condition upon a restricted diet and, as is so frequently and needlessly done, prohibiting games within reason, since experience has proved that these regulations are not consistent with their welfare.

Sugar (a trace)		3

Puberty.

Occasionally a boy has entered school as young as the age of 12·75, and once a boy came as late as 16·75; but in all other cases the age of entrance was between 13 and 15 years. Between these years 317 had already attained the stage of puberty; while, however, many have reached puberty at 13, its advent in a few cases has been deferred until after the age of 15.

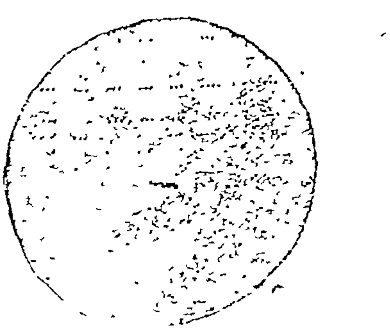
Rugby.

A CASE OF TYPHOID FEVER: A NOTE ON THE BACTERIOLOGICAL EXAMINATION OF THE BLOOD.

By WINIFRED MUIRHEAD, L.R.C.P., L.R.C.S. Edin.,
ASSISTANT MEDICAL OFFICER, STIRLING DISTRICT ASYLUM, LARBERT, N.B.

In The Lancet of July 27th[1] there is a note on a paper published by Dr. W Coleman and Dr. R. H. Buxton on the subject of bacteriological examination of the blood in typhoid fever; it appeared to me of interest to record the following case:—

In March last a female patient was admitted to the asylum suffering from acute delirious insanity with a history of illness ten days in duration. Her mental condition was one of great excitement and confusion, with hallucinations of sight and hearing. Physically the patient was found to have an enlarged and palpable spleen, discrete



Blood film, showing *bacillus typhosus.*

---

[1] The Lancet, July 27th, 1907, p. 242.

cultivate themselves are in every case '*foci of lowered bacteriotropic pressure*,' and that the deficit of antibacterial substances in such foci can be accounted for by the fact that bacteriotropic substances are absorbed whenever blood fluids come in contact with bacteria, and by the fact that in the case of foci which are cut off from the blood stream the conveyance of bacteriotropic substances to the focus of infection by the lymph stream can only rarely keep pace with the afore-mentioned absorption. This premised with regard to the conditions which are common to all bacterial foci, I may here conveniently direct attention to special conditions which obtain (*a*) in infections of serous membranes where serous effusion has taken place, (*b*) in abscesses, (*c*) in sinuses, and (*d*) in association with brawny swelling of the subcutaneous tissues.

(*a*) *Conditions which obtain in the case where bacteria are growing in, or in contact with, serous effusions.*—These are well exhibited in connexion with tuberculous peritonitis. Here, as my fellow worker, Douglas, and I have already shown, the ascitic fluid has in every case a much lower opsonic index than the circulating blood. It follows that the bacteria which are cultivating themselves in, or in contact with, such ascitic fluid are not exposed to the full bacteriotropic pressure of the circulating blood. We have here, as I have already pointed out, an explanation of the success which has attended tapping, and in particular laparotomy, in connexion with tuberculous peritonitis. That success is satisfactorily accounted for by the replacement of a stagnant lymph which has forfeited much of its antibacterial virtue by a fluid of higher efficacy freshly derived from the circulating blood. Manifestly we should be neglecting a very important element in the treatment, if while aiming at the destruction of bacteria in a serous membrane by processes of immunisation we were to fail to take into account the fact that the bacteria which are the object of our attack are cultivating themselves under a lowered bacteriotropic pressure.

(*b*) *Conditions which obtain in abscesses.*—In abscesses the conditions are more complicated. Here we have to take into account not only the absorption of bacteriotropic substances by bacteria, but also another factor which does not come into consideration in the case of ordinary serous effusions. This factor is the liberation of a tryptic ferment from the leucocytes. Such liberation occurs, as Opie has shown, whenever these formed elements disintegrate in pus. It is clear that as soon as—under the influence of autolysis or bacterial action—leucocytes have disintegrated in an abscess in numbers sufficient to abolish the opsonic and antitryptic power of the surrounding fluid, not only the normal bacteriotropic defence, but also the leucocyte defence will be thrown out of gear. I have neither the time nor the data to discuss with you here certain important but incidental issues which suggest themselves in this connexion, in particular the issue as to whether the liberation of tryptic ferment in the abscess—which Opie has brought into association with the destructive and burrowing action of pus—may not also account for the paralysis of all phagocytic effort which sooner or later overtakes the leucocytes in every focus of suppuration and for the frequent sterilisation of the contents of an abscess. It is, however, incumbent on me to point out to you that where we are aiming at the destruction of the bacteria in a suppurating focus by the agency of opsonins and leucocytes, and are aiming at the same time at the safeguarding of the tissues from the digestive action of the pus, it would be futile to attempt this task without making provision for the replacement of the tryptic and non-opsonic pus fluid by an antitryptic and opsonic fluid freshly derived from the circulating blood.

(*c*) *The conditions which obtain in sinuses.*—The conditions with which we have to deal in a sinus where that sinus is freely discharging pus are, I take it, essentially similar to those which prevail in an abscess which is discharging without emptying itself. In other words, we have a pus fluid which possesses a low opsonic power, and which exerts upon the tissues a digestive effect—a digestive effect which makes itself manifest to the eye in the case of a discharging sinus in the sodden and unhealthy appearance of the skin around the orifice. In the case of a choked sinus we have to deal with conditions which might be compared to those which would obtain in a well if the water which originally flowed into it had deposited an insoluble element in such a manner as to choke up all the conduits of supply. We can easily conceive how, no the walls and floor of such a well, forms of life might maintain themselves which would be quite incompetent to penetrate into the surrounding soil, or to hold their own in the face of a copious output of water. A dry sinus is, if I understand the situation aright, analogous to just such a choked well, the obstacles to the inflow of lymph being, on the one hand, the density of the granulation tissue, and on the other hand, the lining membrane of fibrin which clothes the walls of the sinus. If these are in reality the conditions under which bacteria maintain themselves in a sinus, we shall need for their dislodgment something more than a mere increase of the bacteriotropic power of the blood and circulating lymph.

(*d*) *The conditions which obtain in "brawny swelling."*—Next in order we have to consider the case where we have a focus of bacterial growth in tissues which are affected with 'brawny swelling.' I take it that in brawny swelling we have conditions which are, in the respect that the bacterial growth is cut off from the blood and lymph stream, analogous to those which have just been under consideration in connexion with sinuses. It is in the nature of a minor difference only that in brawny swelling the bacterial growth is isolated from the blood and lymph stream by the clotting of the lymph in the lymphatics, while in the case of a dry sinus the isolation of the bacteria is brought about by the clotting of the lymph on the surface of granulation tissue.

THERAPEUTIC PRINCIPLES WHICH EMERGE FROM THE CONSIDERATION OF THE CONDITIONS WHICH OBTAIN IN A BACTERIAL FOCUS.

A strict regard for the logical development of my subject matter would perhaps dictate that I should at this point embark upon the study of the phenomena of auto-inoculation, reverting afterwards to the consideration of the therapeutic measures which may be employed for dealing with the difficulties which are created (*a*) by the absorption of bacteriotropic substances in the bacterial focus; (*b*) by the liberation of tryptic ferment that takes place when leucocytes are broken down; and (*c*) by the obstruction of the lymph flow. It will, however, perhaps be more convenient if I discuss the therapeutic measures by which we may deal with these difficulties while the situation which we have in each case to confront stands out clearly before your minds. The general principles which ought to inform all our therapeutic measures are the following:—*We must provide for the conveyance of bacteriotropic substances into the focus of infection. In the case where an accumulation of stagnant fluid in the focus of infection effectually prevents the entrance of bacteriotropic substances we must as a preliminary measure draw off the fluid which occupies that focus. In the case where there are other obstacles to the free streaming of lymph through the focus of infection we must remove those obstacles.*

(*a*) *Conveyance of bacteriotropic substances into the focus of infection.*—The douching of the focus of infection by a stream of lymph fresh from the blood-vessels can in the case where the tissues are uninjured and the lymphatic channels are unobstructed, be effected by determining by the agency of heat or any other rubefacient a larger blood-supply to the region affected. It can also—as in Bier's method—be effected by banking up the blood in the veins in such a manner as to increase the hydraulic pressure in the capillaries.

(*b*) *Removal of stagnant fluid from the focus of infection in the case where this prevents the lymph which transudes from the blood-vessels finding proper access to the infecting bacteria.*—In the case where the lymph can effectively make its way through the focus of infection, permeating every part of it, access of the bacteriotropic substances to the infecting bacteria will manifestly be provided for by the activation of the lymph stream quite apart from any operative interference. In such a case the stagnant fluid which occupies the bacterial focus will—whether for good or for ill we must afterwards consider—be driven on into the general circulation by the *vis a tergo* of the activated lymph stream. Where this method of dispersion is inapplicable, or where for any reason it is contra-indicated, the evacuation of the stagnant fluid by operative measures will obviously be desirable. In the case where we have in an abscess a tryptic fluid which is eating its way into the surrounding tissues[4] such evacuation will not only be desirable but imperative.

---

[4] It is perhaps worth noting that the fact that an abscess gives fluctuation does not by any means furnish sufficient warrant for concluding that it contains a tryptic fluid and that operative measures must be resorted to. Again, even where the contents of an abscess have by the disintegration of leucocytes already acquired tryptic powers, it may still be practicable to abolish that tryptic power and to effect resolution by leading into that abscess cavity a sufficient quantum of antitryptic lymph.

Utrecht (in Dutch). Translations of each are also provided—in English for the first and second, in German for the third and sixth, and in French for the fourth and fifth. The article by Erasmus is a general encomium on the art of medicine, and contains a short notice of what would now be called a case of multiple personality. The example taken from the writings of Leeuwenhoek is a communication made to the Royal Society of London in 1688, in which he describes the blood corpuscles of the tadpole, frog, and fish and announces his discovery that in these creatures the arteries conveying blood from the heart led into the veins which returned the blood to the heart. The paper by Swammerdam is on various phenomena of contractility in the muscles of the frog. Boerhaave is represented by a public oration which he delivered before the University of Leyden in 1703. In a portion of this address he draws attention to the necessity for medical men having a good knowledge of the physical sciences, specially instancing geometry, mechanics (now subdivided into statics and kinetics), machine construction (*fabrica machinarum*), pneumatics, hydrostatics, and chemistry. This list of extra-medical subjects is quite as long as could have been expected at that period; microscopy, of course, was included as a department of anatomy and physiology. Gaubius was professor of chemistry in the University of Leyden, and the article by him now published was a lecture in which he claimed for chemistry a place among the subjects of the university curriculum (*chemiam artibus academicis jure esse inserendam*). The style of this lecture, which was delivered in 1731, is decidedly rhetorical and florid. Professor Donders of the University of Utrecht was, of course, a pioneer of modern ophthalmology. The specimen of his literary work given in the present volume is, however, a lecture delivered in 1848 on the Principle of Harmony in Animal Life. This principle is shown in the mutual adaptation of animals and their environment. In South America, for instance, the llama confines itself to the mountain regions of Chili and Peru without ever descending to the plains of Brazil. The reindeer, a native of Lapland, suffers from the summer heat when it is brought into lower latitudes; and, on the contrary, monkeys and tropical snakes require to be kept warm in northern climates. Full-page portraits of each of the authors except Swammerdam are given, and there is a large folding plate illustrating the microscopical discoveries described in the paper by Leeuwenhoek. The general appearance of the volume as regards typography and binding is tasteful and the monographs which it contains, Leeuwenhoek's in particular, are interesting to the student of the history of medicine.

LIBRARY TABLE.

Upon the Therapeutic Properties of the Waters of Baden (Switzerland) in the Treatment of Gout. By Dr. PAUL RÖTHLISBERGER. London: John Bale, Sons, and Danielsson, Limited. 1907.—Within half-an-hour by rail from Zürich, the "Swiss Baden" continues to be frequented by sufferers from gout, acute and chronic, and for reasons well set forth in this tractate by the well-known consultant physician, Dr. Röthlisberger. Known to the ancient Romans, it has a special note of commendation from Tacitus, after which it seems to have fallen into neglect, to re-emerge, however, into fame and popularity in the fifteenth and sixteenth centuries. Since then it has, like other resorts of the kind, gone through many alternations of fortune, losing favour in the eighteenth century and regaining it in the nineteenth, till now, in the century not yet in its teens, it attracts a larger *clientèle* than ever. All these vicissitudes are graphically described by Dr. Röthlisberger who treats us to a "march past" of the resident physicians, mediæval and modern, under whom its fortunes have waxed and waned, and then proceeds to state and to strengthen its special claims on the victim to gout. These are, put shortly, its activity in promoting the excretion of uric acid; its influence upon the formation of uric acid in the body; and its effects in counteracting that demineralisation in gout which has been noticed by Gaube, Lahmann, and other authorities. Illustrating these positions by expert analyses of the waters and by clinical experience of their effects, Dr. Röthlisberger appends to his work a copious bibliography from which the scientific or professional reader can check or confirm the conclusions arrived at, which are: that the sulphur waters of the Swiss Baden employed externally and internally are of distinct benefit in gout, whatever may be the theory of its "pathogenesis"; and that be the predisposing causes of gout and the conditions favouring its development what they may the experience of centuries indicates the said waters "as a therapeutic measure which should not be disregarded or lightly discredited."

Eating to Live, with Some Advice to the Gouty, the Rheumatic, and the Diabetic. By JOHN JANVIER BLACK, M.D. London and Philadelphia: J. B. Lippincott Company. 1906. Pp. 412. Price 6*s.*—Under this somewhat whimsical title Dr. Black, who dates his preface from Delaware, U.S.A., has written a useful treatise on the principles of dietetics. Moderation in both eating and drinking is what he chiefly enjoins, together with the avoidance of haste and preoccupation at meal times. He therefore disapproves of several well-established usages, such as eating for mere social enjoyment and to pass away time. This he considers to be tampering with the digestive organs, and there is a characteristic American institution which he does not scruple to condemn in his reference to "the horrors of the quick lunch where all the laws of health as to digestion are violated." In his recommendations with regard to the selection of a suitable dietary Dr. Black makes much use of Professor Chittenden's experiments with "eating squads" composed of men of various ages. An average individual in the United States is said to consume daily 17 grammes of proteins, whereas seven grammes appeared to be sufficient for the members of Professor Chittenden's squad. Dr. Black therefore concludes that too much meat is eaten and he points out that this great nitrogenous excess is very trying for the kidneys. He particularly denounces the profusion of the daily bill of fare on board ocean-going passenger steamers and asks: "How is it possible for the system to rid itself of the waste from all this inordinate gourmandising?" No doubt his view is correct, but it must be remembered that the circumstances are exceptional, for passengers at sea find time to hang very heavy on their hands, and the hours spent at table are a welcome relief to the prevailing ennui. On the other hand, one of Professor Chittenden's physiologically correct menus, which Dr. Black quotes with approval, would create dismay in the mind of the ordinary diner-out. A great deal of miscellaneous information with regard to various kinds of meat, fish, fruit, edible fungi, and other foodstuffs is given in these pages, together with good advice on diet at various periods of life and in a number of diseases.

Women's Health and How to Take Care of It. By FLORENCE STACPOOLE. Second edition revised. London: Simpkin, Marshall, Hamilton, Kent, and Co. Bristol: Wright and Co. 1906. Pp. 165. Price, stiff boards, 1*s.* 6*d.*; cloth, 2*s.* 6*d.*—We are glad to see that the authoress has brought out a second edition of this little work. It contains in clear and simple language many things as to the care of their health that all women ought to know. The ignorance which many women display on the subject of the common disabilities of their sex is most astonishing and books like this, if they only can be placed in the hands of those for whom they are intended, understood, all methods of bacteriological diagnosis in which we arrive at the nature of the infection by a process of induction from a measurement of the bacteriotropic content of the blood are methods which have as their aim the detection of the changes which are produced in the blood by the agency of auto-inoculations. The following three examples will suffice to make this clear. The agglutination test in typhoid fever—whose authorship was claimed by Widal on the plea that the increased agglutinating content of the serum was something other than the result of an immunising response evoked by an auto-inoculation—is now by common consent recognised to be a test which depends—as Gruber, with his collaborators Durham and Grünbaum, from the very first discerned—on the detection of products of immunity produced in response to an auto-inoculation. "The thermostable opsonin test," whose diagnostic value was first demonstrated by Reid and myself, furnishes in like manner evidence of an immunising response to a foregoing auto-inoculation or, as the case may be, to an inoculation of the corresponding bacterial vaccine. Exactly the same thing holds true of the "absorption of complement test" recently so extensively exploited by Wassermann.

It will be clear that in all these cases diagnosis has perforce to wait upon spontaneous auto-inoculation. Such spontaneous auto-inoculation may, as we have seen in connexion with localised infections, be indefinitely deferred. It therefore marks a distinct step in advance when we come to realise that we can, in the case where the focus of infection is accessible, supply the place of the spontaneous auto-inoculation which makes default by the induction of an artificial auto-inoculation.

Let me say in this connexion that we have, by the agency of massage, active muscular movements, Bier's bandaging, or, as the case may be, other methods of artificial auto-inoculation, combined in each case with the measurement of the opsonic index before and after such event, obtained diagnostic results which have up to the present in every case been borne out by the subsequent history of the case. I would note here—for it is germane to the subject-matter under discussion—that we have had recourse to auto-inoculations associated with measurements of the opsonic index not alone for the preliminary diagnosis of the bacterial infection but also for the purpose of obtaining information with regard to the progress of the patient. Where an artificial inoculation can no longer be induced in a focus which previously could be influenced we are entitled to conclude that the focus of infection is extinct. Where an auto-inoculation can still be induced we may be assured that the focus of infection is still aglow.

DISCUSSION OF THE COMPARATIVE MERITS OF TREATMENT BY ARTIFICIALLY INDUCED AUTO-INOCULATIONS AND TREATMENT BY THE INOCULATION OF BACTERIAL VACCINES.

It has, I take it, by this time come home to us all that we have in spontaneous auto-inoculation, in artificially induced auto-inoculation, and in the inoculation of bacterial vaccines the three great agencies by which immunising responses can be evoked in the organism. Comparing first the immunising effects which are achieved by auto-inoculations taken generally with those which are achieved by the inoculation of bacterial vaccines it may, I think, be laid down with confidence that the former method of immunisation is far more expensive—expensive in the sense that the patient obtains a much smaller yield of protective substances for an equivalent of intoxication. Quite a number of other considerations come into account where we have to elect between treatment by artificial auto-inoculations and treatment by the inoculations of bacterial vaccines.

First in order comes the question of an eventual risk of disseminating living bacteria in the organism. It will be appreciated that the employment of auto inoculations, since here, of course, living cultures are exploited, can never be entirely dissociated from this risk. There is no such risk where we operate with sterilised bacterial vaccines.

Next in order of importance comes the question of dosage. It will be plain that in all auto-inoculations we operate not only with living cultures but with unmeasured doses. Where we have to deal with a very considerable focus of infection, or, failing this, where in connexion with a smaller focus the irrigation with lymph is very searching and unduly prolonged, there will be washed into the general blood and lymph stream an excessive dose of the bacterial products. Where, on the other hand, we have to deal with a small focus of infection, or where in the case of a larger focus irrigation with lymph is continued for too short a time, too small a vaccinating dose will come into application.

Again, where by reason of a gradual restriction of bacterial growth effected by immunisation, or where by reason of a repeated draining off of bacterial products under the influence of Bier's treatment or of massage, diminishing quantities of bacterial products are available in the focus of infection, there will come into application diminishing doses of vaccinating elements, while there may quite well be required, for the maintenance of adequate immunising responses, undiminished, or, as the case may be, increasing, doses of these elements.

Lastly, we have to keep in view, on the one hand, the fact that methods of auto-immunisation are applicable only in the case of foci which are superficially situated or are positioned in the extremities; and, on the other hand, the fact that the demands which are made upon the patient's time and the work which is thrown upon the controlling physician are, in the case where auto-inoculation methods are employed, much more serious than in the case where inoculations with measured doses of bacterial vaccines come into application.

Let it be noted in conclusion that the issue as between treatment by auto-inoculation and treatment by the inoculation of bacterial vaccines which has just engaged our attention reveals itself upon consideration to be largely an academic issue.

Whether we set out to activate the lymph stream on purely empirical principles, as Bier does with his bandaging, or the ordinary surgeon with his hot fomentations, or the masseur with his massage, or the radio-therapist with his radio-therapy, or the physician with certain of his drugs and hypodermic injections; or whether, as immunisators, we employ these methods with the sole intent of conveying bacteriotropic substances from the blood into the focus of infection, there will in each case be achieved in addition to the local effect which was intended also an unsought artificial auto-inoculation. That auto-inoculation may produce quite unintended effects; unintended effects in the form of an amelioration in bacterial foci remote from the seat of application of the bandage are not unfrequently obtained in connexion with Bier's treatment. Unintended effects are seen also in connexion with massage. I have, in connexion with the massage of gonorrhœal joints, seen such effects both in the form of amelioration and in the form of aggravation of the condition of untreated joints.

It equally holds true that when as immunisators we apply a Bier's bandage, or massage, or any similar device, thinking only of its auto-inoculating effect, there will in each case be achieved, in addition to the general immunising effect which was aimed at, also an unintended beneficial local effect caused by the conveyance of antibacterial substances into the focus of infection.

QUESTION AS TO WHETHER INOCULATIONS OF BACTERIAL VACCINES MAY BE UNDERTAKEN IN BACTERIAL INFECTIONS WHICH ARE ASSOCIATED WITH SPONTANEOUS AUTO INOCULATIONS.

When the question as to the possibility of inoculating bacterial vaccines with safety and advantage to the patient in septicæmic infections, and in general in those types of infection which are associated with spontaneous auto-inoculations, comes up for discussion we are confronted with the *a priori* objection that, inasmuch as the vaccinating bacterial products are here already circulating in the blood, producing an intoxication, it would be plainly irrational to expect from the incorporation of further bacterial elements anything other than an aggravation of that intoxication.

To this argument two different rejoinders can be made. On the one hand, the objector may be confronted with the favourable results of actual experiments in which bacterial vaccines have been inoculated in septicæmic infections. On the other hand, an endeavour may be made to bring it home to the objector that recourse to the inoculation of bacterial vaccine in septicæmic conditions is not the irrational proceeding that it might at first sight appear.

I may conveniently here address myself to this last task, leaving for future consideration the results which have been actually obtained by inoculation in septicæmic disease. Let me in this connexion hark back to what was said in an earlier part of this lecture on the subject of the probable place of origin of the antibacterial substances. If I am right in supposing that the bacteriotropic substances

THE
BRITISH MEDICAL ASSOCIATION.

MEETING AT EXETER.

THE SECTIONS.

PATHOLOGY.

WEDNESDAY, JULY 31ST.

The PRESIDENT of the Section (*Professor* R. MUIR of Glasgow) at once entered into the business of the day by asking Dr. WILLIAM HUNTER (London) to open the discussion which had been arranged on the subject of

Pernicious Anæmia and Allied Conditions.

Dr. Hunter said that he could best contribute to the purposes of the discussion by confining himself more particularly to the great problem of the unity or plurality of that condition first described by English observers under the title of idiopathic anæmia—a problem which continued to divide observers into two great and hostile camps. His own observations on the subject extended over 21 years of work and would be grouped under two headings: (1) the character of the observations on which the conclusions were based; and (2) the character of the conclusions formed. For and against the individuality of this admittedly most severe and fatal of all forms of anæmia he should illustrate and summarise his remarks by the aid of lantern slides of the observed lesions, curves and charts, and a series of schematic tables. The character of the observations had been in succession experimental, anatomical, clinical, chemical, diagnostic, and finally etiological, bacteriological, and historical. The pathological observations of the last seven years regarding the significance attached to the infective lesions subsequently to be described were based upon a general pathological experience extending over 1000 post-mortem examinations and the clinical observation of some 50 cases of the disease. *The results* showed conclusively that Addison's anæmia was not only a remarkable form of anæmia but a remarkable specific infective disease with characteristic etiology, and its mode of onset, clinical features, and course should be separated off, once and for all, from all other forms of anæmia in the manner indicated in the accompanying diagram (Scheme I.). With the assistance of other schematic tables Dr. Hunter traced the history of pernicious anæmia from the early records of Addison of an idiopathic anæmia without discoverable cause, no distinctive pathology, and without symptoms other than those due to the anæmia itself (1855–1871); through the school of Biermer, when the etiological factors were put down as poverty, chronic discharges, puerperal conditions, and so on, in addition to all the ordinary causes of anæmia, with "predisposition" as a support to any or all of these; the anatomical changes were stated to be of no pathogenetic significance whatever, although the hæmorrhages and the bone marrow changes were noted by many writers; and the symptoms dismissed as having no special features and little diagnostic value (1871–1888), so that the affection came to be regarded

more tractable to vaccine-therapy than a focus of infection in the deeper tissues which has not yet found vent, or a focus which has not yet penetrated to the lymph-bearing stratum below. It will be clear that as soon as such communication has been effected the lymph stream which has been tapped in the deeper tissues will well up through the floor of the ulcer, coming in contact as it does so with the infecting micro-organisms.

(c) *Infections of the Skin.*

Infections of the skin fall naturally into two categories. Where the infected skin is comparatively dry and scaly and non-vascular we are dealing with a form of infection which is, in my experience, extremely intractable to vaccine-therapy. A typical example of such an intractable type of skin infection is furnished by the superficial scaly form of lupus which has from the point of view of its superficial resemblance to psoriasis been, very appositely, denoted '*lupus psoriasis.*' Where the microbes affect a region of the skin which is vascular, or where, as in staphylococcal sycosis, the microbes penetrate deep into the skin, we have forms of infection which are very tractable to vaccine-therapy.

(d) *Infections of Mucous Membranes and of the Glands and Ducts which stand in Connexion with Mucous Membranes.*

Infections of mucous membranes are, in my experience, very readily influenced by vaccine-therapy. Many very successful results have been obtained in connexion with the most various infections of the middle ear, antrum, nasal sinuses, dental alveoli, and salivary glands; also in connexion with coli infections of the intestinal mucous membrane and gall-bladder; and again in connexion with many different infections of the uterus, urinary bladder, and urethra.

I would direct your special attention to two points in connexion with these infections. The first relates to the question of mixed infection. It will be plain to consideration that where we are dealing with bacterial infections of mucous membranes which normally harbour on their surface numerous species of bacteria, the restriction of the numbers of the peccant micro-organism—a restriction which can readily be achieved by vaccine-therapy—is often followed by a multiplication of some other competing form of micro-organism. My second point relates to the case of bladder infections. Here we have generally, in addition to the infection of the mucous membrane, to deal with a bacteriuria. Now it does not by any means follow that the extinction of the infection in the mucous membrane and the abatement of the cystitis—results which are generally readily obtainable by vaccine-therapy—will be followed up by a cessation of the bacteriuria. This last-mentioned result, however, has, be it noted, already been obtained by the agency of vaccine-therapy in a considerable percentage of the cases which I have treated.

(e) *Infections of Sinuses.*

In my experience very successful results are obtained in these cases when the inoculation of bacterial vaccines is combined with the course of treatment by local lymphagogues which was suggested when we were considering the treatment of sinuses.

(f) *Mixed infections.*

Before discussing the results which have been obtained by vaccine-therapy in connexion with mixed infections an introductory word may perhaps be appropriate. While the suggestion that mixed infections must be expected in suppurative processes occurring in connexion with surfaces which harbour microbes may quite well be universally acceptable, as not breaking in upon any accepted belief; the suggestion that the question of mixed infection must perforce be considered in connexion with every case of phthisis, lupus, tuberculous caries, tuberculous cystitis, and tuberculous ulceration will, in the very nature of things, be unacceptable to many clinicians. Such a suggestion will be felt to call in question both the clearness of vision of those who in connexion with these diseases have clamoured for anti-tuberculous remedies only, and the critical acumen of those who, without taking into account the fallacies which are incidental to clinical methods, confidently undertake to adjudicate on anti-tuberculous remedies by the observation of their clinical effects upon cases where in addition to the tubercle bacillus other pathogenetic microbes are at work.

Be it acceptable or unacceptable, there is no escape from the fact that practically every case of suppurating lupus is complicated by staphylococcus infection, and that the majority of aggravated cases of lupus are complicated by a streptococcus infection. What holds true of lupus holds true, *mutatis mutandis*, of every tuberculous affection to which microbes can find access.

Having appreciated the magnitude and the far-reaching nature of the issues involved in the treatment of mixed infections we may come to the question of the results achieved in these cases by vaccine-therapy. We have two cases to consider.

(a) *Case where vaccine therapy is directed to the destruction of only one of the infecting microbes.*—In a few instances—notably in two cases where there was found in association with an atypical furunculosis a mixture of streptococci and staphylococci—the extinction of one of the microbes under the influence of the corresponding vaccine has indirectly led to the extinction of the other. This event is, however, extremely exceptional. In most cases the employment of vaccine-therapy directed to the destruction of a single species of microbe leaves the other species quite unaffected. It may even—and this applies in particular to surface infections of mucous membranes or ulcers—conduce to the multiplication of the other—i.e., the originally competing microbe.

(β) *Case where vaccine therapy is directed to the destruction of all the infecting microbes.*—Where in cases of mixed infection measures are taken to immunise the patient against each of the different infections very successful results have been achieved. Successful results have been achieved notably in the case of lupus, cystitis, and endometritis. While naturally the task of the immunisator is more laborious and more intricate in the case where two or three different vaccines are employed, it would seem that the organism of the patient does not find the task of responding to a series of different vaccines (always supposing that each of these is administered in appropriate and properly interspaced doses) more difficult than the task of responding to one variety of vaccine only.

(g) *Generalised Infections.*

In association with my fellow-workers I have up to the present treated by vaccine therapy some half-dozen cases of Malta fever and an equal number of cases of streptococcal septicæmia. In each of the cases of Malta fever the course of the disease would seem to have been favourably influenced—the clinical improvement occurring in each case in association with an increased development of antibacterial substances in the blood. In the cases of streptococcal septicæmia the results have been as follows: In two cases—one of these being a case of malignant endocarditis—a complete cure was achieved, in each case in association with a very satisfactory immunising response. In a third case—also a case of malignant endocarditis—the high temperature which had lasted for three months before vaccine-therapy was resorted to came down to the normal under the influence of the inoculations, the patient making an excellent immunising response. In this case death by cardiac complication occurred on the fourth day after defervescence. In three other cases of streptococcal endocarditis the patients succumbed, having in each case failed to make any immunising response to the inoculations.

University of Cambridge.—The General Board of Studies will proceed early in the Michaelmas term to appoint to a University lectureship in botany which will be vacant by the resignation of Mr. A. W. Hill. The annual stipend is £100. Applications should be made to the Vice-Chancellor before Oct. 11th.—The dates for the examination in sanitary science are: Part I., Wednesday, Oct. 2nd; and Part II., Monday, Oct. 7th.

The Royal Cornwall Infirmary, Truro.—The annual meeting of the subscribers of this institution was held at Truro on August 12th. The medical report stated that during the past 12 months 417 in-patients had been admitted, a decrease of 56 compared with the preceding year; 1057 out-patients had been treated compared with 1165 in the previous twelve months. The financial statement was satisfactory and showed that a legacy of £1000 had been received from the executors of the late Mr. W. Jackson. The report added that 119 patients had been sent to the convalescent home at Perranporth. Mr. G. Petherick has recently given a complete x ray apparatus to the infirmary. The meeting decided, with the approval of the medical staff, to provide a private nursing institution in connexion with the infirmary.

dependent on the poverty of the blood, a hæmatological conception of the pathology and symptomatology of the disease which had a tendency to mislead and confuse those who had not carefully followed and assimilated the constructive evidence accumulated by the speaker. Dr. Hunter then detailed, with the help of lantern slides, the changes, naked-eye and microscopical, that accompanied the lesions of the gastro-intestinal area, as shown in the tongue, stomach, and intestine, comparing and contrasting them with the appearances in similar situations in cases of other forms of anæmia, cancer, and the like.

Dr. G. **Lovell Gulland** (Edinburgh) next contributed to the discussion some theoretical considerations on

The Pathogenesis of Pernicious Anæmia.

He stated that he should present some theoretical points for consideration. In the first place, although the exciting causes of pernicious anæmia might be very various, there must be some one cause common to all cases, since the effect in different cases upon the blood and marrow was so similar and was apparently influenced by definite laws. The disease was generally regarded as a reversion to an embryonic type—in other words, that pernicious anæmia was a condition resulting from the presence of a hæmolytic toxin which after the normoblastic process of regeneration had been exhausted in the endeavour to repair the destruction impelled the individual to substitute the megaloblastic process and thus produce an embryonic type of blood. It would, however, appear probable that a process of inhibition rather than destruction occurring in subjects who had some congenital or acquired weakness of the bone-marrow underlies the observed phenomena. In support of this contention he adduced the inhibitive influence of the toxin of pernicious anæmia upon the development, or at least the appearance in the blood of the neutrophile series of cells, and suggested that the relative lymphocytosis which was so common a feature of pernicious anæmia was actually a leucopenia of polymorphonuclear neutrophiles, although in the remissions of the disease there were usually many myelocytes in the bone marrow. Dr. Gulland then referred to his own interpretation of Dr. Goodall's researches on embryonic hæmatogenesis, and suggested that the erythroblasts without hæmoglobin were not derived from primitive megaloblasts but directly from mesenchyme cells, and that they must be regarded as peculiar to mammals in which the megaloblastic type of blood formation was embryonic only and did not persist throughout adult life. It was well known that a certain number of these megaloblasts were to be found in all mammals as a survival of embryonic life; if then the toxin of pernicious anæmia inhibited normal blood formation the demand of the organism for hæmoglobin carrying cells would stimulate these megaloblasts into activity, and produce the typical clinical picture of megaloblastic blood. These cells not being suited to the needs of the mammalian organism it was the products of their destruction that appeared as iron in the liver and urobilin in the urine. In conclusion, Bunting's experiments with ricin and saponin were referred to as showing that toxic influences produced conditions closely resembling those present in pernicious anæmia, and controverted Hunter's assumption that the blood destruction which he maintained was the feature of the disease took place in the portal system.

Typical Blood Characters in Pernicious Anæmia and Allied Conditions.

Dr. O. H. **Melland** (Manchester) then briefly referred to the distinctive characters of the clinical symptoms of pernicious anæmia which were present in the majority of cases, but reminded the members of the section that such symptoms were occasionally absent, and stated that he wished to emphasise the pathognomonic importance of the blood changes which were so readily observed microscopically and further contended that treatment could only be successfully carried out when controlled by frequent blood examinations to note the effect of the measures employed. He then demonstrated a series of ten excellent lantern slides of blood films typical of various conditions. The first three were from cases of pernicious anæmia and showed respectively megalocytes, reduction in number of erythocytes, irregularity in their size and shape (but large average size) and their granular degeneration, and the slight reduction in number and the irregular but large size of the red cells in a convalescent case. The fourth from one of the cases after two and a half months' treatment showing the return of the blood cells to the normal type. The fifth, from a case of cancer of the stomach, which resembled clinically pernicious anæmia, showing the normal type of cell although the erythrocytes were reduced in number. The sixth from a case of rheumatoid arthritis, and the seventh, from one of secondary anæmia, showed irregularity in size of the red cells and some poikilocytosis, but an absence of megalocytes. The eighth, from a case of severe chlorosis, showed a few megalocytes, but the vast majority of the red cells were normal in character. The ninth, from a case of carcinoma of the stomach, showed several megalocytes, but the bulk of the red cells were smaller than normal and the cell index was stated to be reduced to 57 per cent. of normal. The last of this interesting series proved a typical case of leukanæmia.

Dr. A. **Gordon Gullan** (Liverpool) then detailed the results he had obtained in

The Treatment of Pernicious Anæmia with Bone Marrow,

premising that in each of the several cases that had come under his observation during the past few years the presence of a definite lesion of the alimentary tract could be demonstrated, which lesion was, he considered, the site of infection, whether microbic or toxic. He related the clinical symptoms of three recent cases and showed by means of curves (indicating the erythrocyte count and the hæmoglobin percentage respectively) the results of treatment. It was noted that the preliminary administration of arsenic in all cases produced a fall in each curve, but withdrawal of this drug and the substitution of fresh bone marrow from the ox, as red as possible, given at every meal in the form of sandwiches, resulted in a steady rise both in the number of red cells and in the amount of hæmoglobin present: in one case from 1,200,000 red cells per cubic millimetre, associated with 37 per cent. hæmoglobin, to 4,500,000 red cells, and 98 per cent. hæmoglobin after two months' treatment, and in another case from 2,500,000 cells, with 67 per cent. hæmoglobin, to nearly 5,000,000 cells and 110 per cent. hæmoglobin. The point which Dr. Gullan emphasised was that notwithstanding the disinclination and nausea on the part of the patient the marrow must be persevered in and its administration pushed to a much greater extent than had hitherto been done.

Professor J. **Lorrain Smith** (Manchester), dealing with

Some Aspects of the Blood Changes in Pernicious Anæmia,

differentiated between true pernicious anæmia and conditions which simulated pernicious anæmia. Of the latter, he instanced the classical cases of infection with bothriocephalus latus in girls which was at first thought to be chlorosis, and mentioned that similar infections with some other intestinal worms, such as tænia solium and tænia medio cannellata, rarely produced anæmia; ankylostomiasis anæmia, which was of the chlorotic type; malarial anæmia, which was frequently of the pernicious anæmia type; and some recent cases of malignant tumour of the bone marrow and fibroma of intestine where the anæmia also presented features resembling pernicious anæmia. In true pernicious anæmia there were presented for study three groups of pathological changes—viz., those connected with the blood and bone marrow, those connected with the gastro-intestinal mucosæ, and those connected with sclerosis of the posterior column of the spinal cord chiefly in the dorsal and cervical segments, and while it was true that experimental study of the disease had failed completely to reproduce pernicious anæmia there was no evidence to contradict the hypothesis that pernicious anæmia was primarily due to a toxæmia. Contrasting chlorosis with pernicious anæmia so far as concerned the hæmoglobin present and the total blood volume, Professor Lorrain Smith stated that in the former disease hæmoglobin was present in normal amount but was *diluted* by reason of the excess of normal plasma in circulation, whilst in the latter a definite *hæmolysis* had taken place and the hæmoglobin was reduced in total amount to, say, 50 per cent. (the lowest observed being 28 per cent.), while the total blood volume might be normal, subnormal, or even increased.

Dr. R. **Hutchison** (London) then discussed

The Anæmias of Childhood

and remarked upon the fact that pernicious anæmia did not occur in early life, which was remarkable whatever view was taken of the etiology of the disease when one considered the existence of all the conditions favouring megaloblastic formation and also the ease with which severe anæmia was produced; for in addition to the readily destructible character of the mass, which grows by [illegible] deposited on it by the [illegible] tion in the distal part and a that most of them are formed [illegible] wall to the proximal micro-organisms, as in the case of gall-stones [illegible] from the coating of moister, fresher material [illegible] appendix was which are present, or which gain access from the cæcum, as suitable nidus for their growth.

The presence of a concretion is therefore a danger and a pretty sure indication of the advisability of the removal of the organ. They are most common between the ages of 15 and 30 years, the period of the greatest frequency of appendicitis, especially in its more severe forms. "It is well known that such lymphoid structures as the tonsils may become tough and fibrous, without the occurrence of any acute inflammatory attack. So will it be to some extent with the appendix, and the results of such chronic inflammatory change will be, at least, impairment of the completeness of peristaltic action. As a result, cæcal contents may enter the interior of the appendix from above, and the material already in that organ will be imperfectly expelled. This may be aided or produced by the anatomical w[illegible] which the appendix is inserted into, or originates [illegible] the cæcum And the common state of affairs is [illegible] find a functional stenosis of the lumen such as that arising from kinking or obliquity of the appendix—i.e., not an intrinsic but an extrinsic stricture. The retained appendicular secretion will later become inspissated. The presence of concretions in calculi may therefore be regarded as evidence of some pathological change."[2] Such a concretion may remain quiet and this is especially so in older people, in whom lymphatic nodules atrophy, the glandular secretions become more scanty, and, we may add, the mode of life less active. In these circumstances the concretion may become quite dry and inert. Their size varies considerably, probably those the size of a cherry-stone are the most common. When I was a student it was taught by some that the cherry-stone was frequently found in the appendix and some of us called it "the trap to catch a cherry-stone." Examination has, however, proved their invariably fæcal origin.

The number of concretions that may be found in any appendix is uncertain; although one is usual I have seen as many as five. To consider that the presence of one of these in an appendix abscess will obviate any necessity for removal of the appendix is, therefore, a mistake. You cannot tell how many are left behind, for they are very rarely faceted. Moreover, it by no means follows that the appendix which remains is not a source of danger on account of its diseased condition, quite independently of the escaped concretion.

The appendix removed from the patient operated on during Tuesday afternoon, May 14th, at the request of Dr. Hector Mackenzie, is a good example of the termination of some of the cases of this kind, where a concretion is associated with a strictured appendix. At the operation the signs of "suppuration" and peritonitis were immediately visible, yellowish, thin, very offensive pus escaping at once on the opening of the peritoneum. The appendix could be felt lying in adhesions to the outer side of the cæcum. To get at these it was necessary to enlarge the wound. The tip of the appendix was lying in front of the right kidney and presented at its apex a gangrenous opening in which a concretion of the size of a cherry-stone was engaged. In order to remove the appendix it was divided between forceps at its proximal attachment, then the meso-appendix separated towards the tip, vessels being clamped as they showed. The attachment to the cæcum was very close and firm in parts and the appendix had to be separated as from a solid bed. When opened up it was found to be a good deal thickened in all its coats, whilst the lumen was very much diminished in size by fibrous contraction which extended from within an inch of the tip upwards towards the cæcum for about half an inch. In the distal part there was the concretion which had not been able to effect its escape, whilst the lining membrane was changed into a gangrenous ulcer which had perforated the wall. In this instance a smaller concretion was found outside the appendix floating in the pus.

Here the concretions were retained in the end of the canal by the stricture, which had been the result of extensive inflammatory changes, not confined simply to the site of the stricture or to the mucous membrane. As the concretion grew in size, and the inflammatory exudation became organised into fibrous tissue and contracted, there came a time when the appendix. A Frenchman, aged 30 years, who never previously had any abdominal trouble, was whilst dressing in the morning conscious of some uneasiness in the lower abdomen on the right side. Jokingly he told his wife that he had an "*appendicite*," but as the crampy feeling quickly escaped away so did his thought concerning it. An hour [illegible] day meal, when walking in the street, he was [illegible] intense abdominal pain that he became [illegible] was greatly affected, as evidenced by [illegible] my state of his skin, by his feeble pulse, and by the [illegible] swelling of the [illegible] iliac fossa. Six [illegible] returned [illegible]

The Effect of External Injury in Producing Appendicitis.

A very interesting question is the [illegible] of a fæcal concretion [illegible] citis after in[illegible]

[illegible] of [illegible] sympto[illegible] other hand [illegible] the injury and [illegible] appendicitis." [illegible] appendix deviated [illegible] 30 out of the 40 abnorm[illegible] concretions; in seven o[illegible] a concretion there was evide[illegible] three, one was flexed on itself, [illegible] unusually short and wide. No ca[illegible] which it has been shown that an inj[illegible] duced an appendicitis in a previously nor[illegible]

The importance of this question will pr[illegible] e evident to all when the new Employers' Liabi[illegible] ith its more comprehensive compensation clauses comes into operation, for it is not unusual to find acute appendicitis as well as more serious conditions, such as perforations of the digestive tract, ascribed by the domestic servant to strain or to overlifting. Now how much more will this be the case when the statement may carry with it a large sum for compensation to the sufferer or her friends. Cycling and motoring have been freely accused of causing appendicitis, but there is nothing in my experience that is so potent a factor in developing that condition, when latent, as the riding of a motor bicycle. Here, again, there is pre-existing disease of the appendix.

In some instances the concretion contains some foreign substance which has been caught up and hidden in the hardening mass after its entrance into the appendix. In all probability many a wanderer beyond the valve of Gerlach is swept back again by a gush of fluid from the irritated chamber into which it has intruded so unexpectedly and passes away with the stream outside, leaving no evidence of its visit.

INCREASE OF DISEASE OF THE APPENDIX IN RECENT YEARS.

There can be no doubt in the minds of those who have been at all intimately concerned in the surgical work of our hospitals during the last 25 years that appendicitis is much more common in every one of its manifestations than it was at the commencement of that period or even half-way through it. The increased number of people who are now enabled to live to the age when its manifestations are most common, in consequence of the greater efficiency of public hygiene and the care of infant life, will not account for it. We used to see a limited number of cases of acute peritonitis which were called idiopathic, when no post-mortem examination was made, but those examined were almost invariably found to be dependent on gross lesion of the appendix. Dr. Samuel Fenwick only found 19 cases of disease of the appendix in the post-mortem records of the London Hospital over a period of 40 years preceding 1884. The number of cases of acute peritonitis has increased, but the naked-eye appearances are not changed as regards the disease of the appendix on which that affection depends.

nitrogen was extremely irregular, cases reported presenting figures varying from 67·9 to 85 per cent. Creatinin was always low. Indican was generally increased, the increase being attributed to intestinal conditions and to putrefaction changes in the extravasated blood. The total sulphur was variable. Albuminoses had been demonstrated in the urine by Laache and Noorden, and Schmidt. Glycosuria was very rare. The occurrence of amino acid, nitrogen, and of lactic acid required further investigation by trustworthy methods. The distribution of iron in pernicious anæmia varied considerably and was difficult of explanation. Post mortem it might be found deposited in the liver and kidney, or in the liver or in the kidney alone.

Dr. F. G. Bushnell (Brighton) presented some preliminary observations on

The Treatment of Pernicious Anæmia by "Vaccines,"

carried out upon four cases of pernicious anæmia occurring in the Sussex County Hospital during the past nine months. First pledging his adhesion to the toxic and hæmolytic origin of the condition, as elaborated by Dr. Hunter, the speaker explained that the treatment of pernicious anæmia was in general so hopeless that he isolated micro-organisms from the mouth and even from the fæces of his cases and prepared vaccines from the bacterial growths thus obtained, which were then utilised for the treatment of his patients. One case was treated successively with vaccines prepared from a streptococcus isolated from the mouth, a staphylococcus from the sockets of the teeth, a colon bacillus from the same site, and a colon bacillus obtained from the patient's fæces. At the commencement of the treatment there were less than one million red cells per cubic millimetre, and the hæmoglobin stood at 20 per cent. After three weeks' treatment marked improvement took place, but a relapse followed and the patient succumbed after three and a half months' treatment. The speaker brought forward his observations in this early stage in the hope that the vaccine treatment of pernicious anæmia might be given a more extended trial by the members of the section.

Dr. Frank M. Pope (Leicester) referred to Dr. Hutchison's remarks upon anæmia in childhood and suggested that some cases of very acute anæmia terminated in chloroma, and in support of his suggestion quoted a case in which deposits of iron were found in collections of bacteria, surrounded by a casing of ferruginous pigment. (This case was fully reported by Dr. Pope and Dr. W. E. Reynolds in our issue of May 18th, 1907, p. 1351.)

The President of the section, before calling on Dr. Hunter to close the discussion, remarked that he concurred in the view that the abnormal blood destruction was the essential feature of pernicious anæmia; and in view of the pigment deposits in the organs and also having regard to the results of comparison with other and allied conditions the bone marrow changes could not be regarded as primary; instancing as other similar conditions bothriocephalus anæmia, pernicious malaria, and saponin poisoning, in all of which a megaloblastic change might be present.

Dr. Hunter then congratulated the section on the mass of data and the wide range of observations that had been presented by the various speakers who had contributed to this discussion and in a few short sentences closed the subject of pernicious anæmia.

Professor Walker Hall then communicated a new method for

The Estimation of Fat in Fæces,

which aimed at the estimation of the total quantity of the fat in the fæces, since this was now considered to yield a more accurate result than the percentage amount of separate portions. Each step had been worked out by comparing the results with similar estimations by the older methods. The method was as follows: 1. Administer a known quantity of fat in the food. Prescribe fluid extract of hæmatoxylin before and after the proteid concerned. 2. Transfer the entire stools to a mortar. Add normal KOH and stir until a homogeneous solution is obtained. Make up to 500 cubic centimetres with distilled water. Shake well. 3. Take 50 cubic centimetres and heat for 20 minutes. 4. Add 50 cubic centimetres 95 per cent. alcohol. Heat for 20 minutes. 5. Add strong HCl until markedly acid (any trustworthy indicator may be used). 6. Heat for 20 minutes. Filter. Evaporate down to 50 cubic centimetres. 7. Take 5 cubic centimetres and determine the percentage in a "milk" centrifugal tube, just as in an ordinary estimation of fat in milk. Or take 20 cubic centimetres in a Schmidt-Werner tube, and make a Schmidt-Werner estimation. After calculation from the dried residue of the aliquot portion of the ethereal extract, multiply the result by 25. If the process was interrupted at 3, then the amount of fat extracted approximated that of the fatty acids. This result deducted from the quantity yielded by the whole process, yielded, according to a number of comparative estimations, an approximate amount for the neutral fats. No definite claim was made for these figures. The method cited had been varied in many ways by the introduction of various fat solvents at all the stages, but their presence had introduced factors of pigment, &c., so they had been discarded.

Dr. Frank Eve (Hull) presented a communication relating to

Peculiar Bodies Found in Some Pathological Cerebro-spinal Fluids.

The author concluded as follows: (1) In certain pathological cerebro-spinal fluids when examined fresh under an oil immersion there may be seen minute filaments with very active lashing movements simulating spirochætæ; (2) these may be seen to originate from the degeneration of leucocytes which extrude finger-like processes which become long filaments, which in turn run into rows of spherical beads; (3) these three stages are to be regarded (presumably) as surface tension effects, the first two stages being in unstable and the last in stable equilibrium; (4) the motility of the filaments, though very life-like, may be explained as the resultant of the Brownian movement of a number of beads on a string, each bead trying to oscillate independently; (5) motile globular bodies consisting of one or more spheres variously linked by filamentous junctions are often seen in cerebro-spinal fluids, sometimes in large numbers—these originate in the same way as the filaments; (6) the occurrence of these filaments and motile globular bodies may prove worthy of note clinically when found in quite fresh cerebro-spinal fluid, as they may then afford evidence of cell degeneration "intra vitam," or be an index of degenerative changes in the central nervous system.

Dr. Bayon (London) remarked that similar filaments could be observed extruded from degenerating white cells from the peritoneal cavity of the guinea-pig that had been first inoculated intraperitoneally with a small quantity of copper sulphate solution (1 per cent. or 2 per cent.) followed an hour or so later by an intraperitoneal injection of leucocytes; and, in reply to a query from the President of the section, Dr. Eve stated that the bodies he described had never been stained by any of the six or eight varieties of dyes that he had employed.

Professor James M. Beattie (Sheffield) communicated some notes on

A Sporozoon in Aural Polypi,

which appeared identical in all respects with a sporozoon he had previously found in nasal polypi obtained from the same district in India and described at the Toronto meeting of the Association. That parasite had been studied by Minchin and Fantham and had been named by them Rhinosporidium Kenealyi. In the light of the present communication, however, it was evident that the name Rhinosporodium must be abandoned. In the aural polypi investigated the young and developing forms in the spore morulæ were very numerous, but all stages could be made out, and by a new method of staining a bright-red chromatic granule could be demonstrated in each of the spores in the spore morulæ. In the small cysts with undifferentiated granular protoplasm there was noted a pale, irregular nucleus and a bright chromatose granule or nucleolus, which in larger cysts becomes broken up into a number of scattered granules. In older cysts still the appearances very closely resembled those shown by the Leishman-Donovan bodies, and later the protoplasms became divided into 15 or 16 rounded spores. By special staining methods there was noted with absolute constancy a larger bright red granule in one particular spore which the speaker suggested might correspond to the blepharoplast of the flagellata, or might be comparable in function to the micronucleus of the infusoria, the spore containing it being a special generative one. Professor Beattie then gave details of the special methods of staining.

OBSTETRICS.

Friday, August 2nd.

Dr. Cuthbert Lockyer (London) read a paper upon

The Operative Treatment of Carcinoma of the Cervix Uteri.

He referred to the fact that no united effort had been made in England to educate the public to recognise the earlier

It contained a soft fæcal concretion in the distal part and a slight inflammatory thickening in the wall to the proximal side of it. Two calcified glands were removed from the mesentery of the small intestine. When the appendix was examined microscopically superficial erosion of the mucous membrane was found. In the concretion was a small irregular fragment of iron, the nature of which was confirmed by Mr. J. E. Adams, then surgical registrar.

We had in this case the early stage of the formation of a stricture, the abrasion of epithelial membrane with a thickening outside, and a foreign body which had been regarded as likely to produce such a condition if it were ever present in the appendix. Had it done so? The condition of affairs is very like that of someone who visits a friend's house and finds from the disarrangement of its contents evidence of attempted burglary. He searches about for a possible intruder and finds a man he has suspected for some time as a man likely to do such a thing if given the chance. The man who was discovered would deservedly be given in charge on suspicion and further inquiries made. A medical man who knew that I was interesting myself in the question of foreign bodies of this kind when under surgical treatment in London produced a piece of metal which he had found in his bread at lunch. It was of somewhat similar kind.

A statement was recently made on the authority of an American physician in an English paper that appendicitis was caused by white flour. The reasons given were the following. When white milled flour was introduced into the cities of a certain State appendicitis began to be prevalent, but it was not yet found in the country. As it became cheaper it was introduced into the villages and appendicitis became common there, yet the negroes escaped. When, however, the flour became so cheap that it was more profitable to buy it than to grind the corn at home, then negroes began to suffer from appendicitis.

It must not be forgotten that the greater prevalence of appendicitis was heard of first in the United States, from which so much of our flour comes, before we saw much of it, and it had been a good deal written about before the reason for doing so was apparent by any increase of the disease in this country. A few years ago windmills were conspicuous in every landscape in England and our corn was ground between stones in the districts where it was grown. It can no longer be ground by the old methods at a profit and flour mills are only to be found in the towns, worked by machinery. But most of our supply comes ready for the market from beyond the seas and it is mostly ground up by metal rollers. The frequency of the disease in certain districts and families would be accounted for by the delivery of flour to that part by a certain baker who would get his flour from regular agents, who in their turn would patronise certain mills. The particles caused by the breaking up of a roller in consequence of a flaw or imperfect material would flow therefore to a definite area of distribution.

Such particles as I have imagined to come from the rollers would necessarily be comparatively few if the amount of flour is considered on the output of any large mill. They would not do harm in the stomach or intestine, but when they did lodge in the human appendix would be dangerous from the small size of its lumen The remedy would be the use of magnets to withdraw such particles from the flour on its way from the rollers to the bags, for although such fragments might not pass the screens through which the finer qualities pass, they might penetrate some of the others, and various qualities might be mixed again by those through whose hands they went on their way to the consumer.

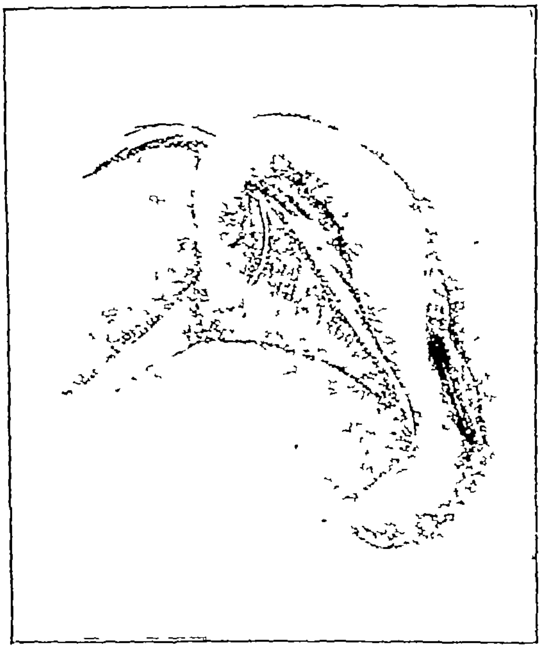
A NOTE ON FOREIGN BODIES IN THE APPENDIX VERMIFORMIS.

The behaviour of a foreign body in this part of the digestive system naturally varies very much according to its nature and size, and it is interesting to observe the history of some cases in which even so-called "innocent" bodies have been found, such as hairs. At times, then, the visitor does not present irritating qualities and is tolerated, no reflex action being excited, or perhaps there is some stiffening of the appendix as a result of previous inflammation, and it cannot give response to the stimulus which it has received, and so clear itself of the intruder.

Dr J. A. Macdougall[6] of Cannes has related an instance which is the best I know showing the disturbance excited by the impaction of an irritating foreign body in the appendix. A Frenchman, aged 30 years, who never previously had any abdominal trouble, was whilst dressing in the morning conscious of some uneasiness in the lower abdomen on the right side. Jokingly he told his wife that he had an "*appendicite*," but as the crampy feeling quickly passed away so did his thought concerning it. An hour after his midday meal, when walking in the street, he was seized with such intense abdominal pain that he became rapidly collapsed. He was greatly affected, as evidenced by his complaints, by the pale, clammy state of his skin, by his anxious, drawn face, by his quick, feeble pulse, and by the intense rigidity of the muscles of the right iliac fossa. Six hours later, after a dose of morphine, the severe pain returned with great vital depression, so that one physician did not think it was worth while to do any operation. The state of the appendix appeared to be normal and so did everything around. "Its proximal third was, however, harder, thicker, and firmer than the rest of the organ, but it bore on its surface no evidence of any notable lesion. On examination after removal it was discovered that a grain of barley still encased in its outer husk was lying transversely to the axis of the appendix with its sharp and pointed extremity buried in the submucous and muscular tissue and stretching—without perforation—the peritoneal covering of the organ." He regarded it as a case of true appendicular colic and considered the personal element was a very important one in the case

Dr. Mitchell has written[7]: "The appendix would seem to act especially as a trap for pointed bodies and for small heavy objects like shot or bullets. Conspicuous amongst pointed bodies are pins, which are the commonest and at the same time the most dangerous of all foreign bodies."

FIG. 1.



A pin in the vermiform appendix, which perforated it by ulceration and caused a fatal peritonitis (From a specimen in the museum of St Thomas's Hospital)

Pins enter the appendix head first as they have come along from the stomach, but they cannot escape in the same way, and perforate by ulceration the wall of the appendix sooner or later, producing localised abscess or more frequently a fatal peritonitis[8] (see Fig. 1, from a specimen in the Museum of St Thomas's Hospital) In a large proportion of these cases hepatic abscess has been a complication.

Of the heavier bodies which enter the appendix by far the most common are shot pellets, obtained through the hurried or careless eating of rabbits or game. If the shot remains favour of panhysterectomy when operating from the abdomen. In the last seven years he himself had performed the operation of panhysterectomy from the abdomen 85 times with only two deaths, one from embolism on the twelfth day and the other from syncope on the sixth day. He looked upon the operation of supra-vaginal hysterectomy as an operation of the last century.

---

[6] THE LANCET, Feb 21st, 1903, p. 506

[7] Johns Hopkins Hospital Bulletin, 1894

[8] It is of interest to recall that the first case of disease of the appendix known, the one recorded by Mestivier in 1759, was caused by a large pin, which had produced ulceration and peritonitis.

Dr. WALTER W. H. TATE (London) was interested to find that Professor Strassmann's experience was the same as his own with regard to the occurrence of carcinoma of the uterus with fibroids, that the presence of both in the same uterus was more common than was usually supposed, but he could not agree that the presence of fibroids was a predisposing cause of cancer; he thought that it was much more likely that both diseases had risen independently in the same woman. He thought that if a woman after 50 years of age, who was known to have a fibroid, suffered from bleeding carcinoma should be suspected. He (Dr. Tate) had noticed that the complications of the uterine appendages were very often associated with impacted fibroids, so that he regarded impaction as an indication for removal of the uterus even if it were giving rise to no symptoms. He also agreed that in fibroids complicating pregnancy abortion should never be procured. Either the patient should be allowed to go to term and the condition dealt with then as might seem best or the uterus with its contents should be removed at once.

Dr. WILSON could not see the advantage of the tongue-shaped incision advocated by Professor Strassmann over the T-shaped one. He had yet to be convinced of the advantage of leaving an ovary; he thought that the present teaching was based on mere assertion. There was no proof that could satisfy any scientific and impartial mind that it was better to leave an ovary. With regard to the relationship of carcinoma and fibroid he was sure that there was such a one. In 40 per cent. of his cases of carcinoma of the body fibroids were discovered; in his cases of carcinoma of the cervix only 5 per cent. had fibroids. Perhaps this might be due to the fact that carcinoma of the cervix occurred in younger women than carcinoma of the body; still the very large percentage of fibroids present in his cases of carcinoma of the body made him suspect there was something more than a casual relation between these two diseases. In his own cases of fibroids he had found complications of the uterine appendages in at least 40 per cent. He thought that the pyosalpinges were due to previous infection and not due to the fibroid—at any rate, as a rule. He thought a great danger of pyosalpinx was that it was likely to cause an impaction of the fibroid.

Dr. SWAYNE (Bristol) was in favour of panhysterectomy and not of supra-vaginal hysterectomy.

Mr. MALCOLM in the case of larger fibroids had obtained better results by abdominal removal, and thought that in panhysterectomy the chief point was drainage. He quite agreed with Dr. Wilson that there was no proof that the woman was better for having an ovary left, and he was led to this view by remarking how very well his patients had done in the cases where he had been forced to remove both ovaries.

Dr. MUNRO KERR remarked that the mortality of abdominal hysterectomy had now fallen to between 2 per cent. and 3 per cent., and he would like to know whether Professor Strassmann had found a lower mortality by the vaginal operation.

The PRESIDENT of the section said that he could not imagine why Professor Strassmann should prefer the vaginal operation to the abdominal. The danger of suppuration and hernia had been mentioned, but anyone who had seen Professor Strassmann operate would see that with all the great care he took the former complication would surely be very rare, whereas he did not think there was any risk of hernia with Professor Strassmann's transverse incision. His own mortality for abdominal hysterectomy was very small and the cases he had lost were due to gross neglect of some point of detail such as infected catgut ligatures. Professor Strassmann had stated that he would not operate on a myomatous uterus without marked reason, or in other words he would leave it alone if it was doing no harm. He could not agree with this. If a patient sought advice with a myoma it was because it was doing harm, and he had found that all patients with fibroids who had consulted him would be better without them. A woman with a fibroid was always in some danger, especially of carcinoma. It had been pointed out that only 2 per cent. of cases were complicated with carcinoma, but the mortality of hysterectomy was now only 2 per cent. He was surprised at Dr. Wilson's remarks about leaving the ovaries, for he could not imagine why a normal ovary should be removed when performing a hysterectomy any more than the woman's nose. If the ovary was healthy why not leave it? and he personally had found that his patients had done much better since he had left their ovaries.

Professor STRASSMANN replied in a very few words and stated that he did not have a higher mortality with vaginal hysterectomy than with abdominal, and that one of his reasons for favouring the vaginal operation was that the patients liked it better; they had no wound to see and there was no risk of hernia. He had had no death after vaginal hysterectomy but had had one after enucleation.

Dr. J. INGLIS PARSONS (London) read a paper on

Notes on a Series of 100 Consecutive Abdominal Sections in Hospital Practice.

He attributed great importance to aseptic measures in operating and considered them the chief means to success. He had lost one patient out of the 100. The cause of death was pneumonia seven weeks after the operation and was not apparently caused by the operation. He advocated myomectomy for single fibroids when it could be done without extra risk. Included in the list was one large fibroma of the broad ligament extending to the umbilicus, with the bladder adherent. Among the cases of ectopic gestation was one of tubal abortion without rupture of the tube. For chronic retroflexion in working women he advocated ventro-suspension, as it enabled them to do their work sooner. For hysterectomy in fibroids he preferred to work as much as possible without forceps on account of the bruising they caused. Seven cases of pyosalpinx, some with ovarian abscesses as well, were operated upon. Of these, two had embolism of a branch of the pulmonory artery, causing dulness over the third of the right lung. Hysterectomy was performed for two cases of persistent menorrhagia where several curettings had failed to stop the loss. Fibrosis of the uterus was the cause in one and recurrent adenoma in the other. The abdomen was closed in three layers. Silk was used for all ligatures and also for suturing the wound, with the exception of the middle layer where silkworm gut was used. The silk was boiled and afterwards put in carbolic.

The PRESIDENT of the section said that he always boiled his silk in corrosive sublimate, as by so doing the silk was impregnated with this substance which prevented any germs that might settle on it during the first three or four days, before the leucocytes were in a proper condition to deal with them, from growing. He also followed Kocher's advice and method to use the thinnest silk possible and never used a thicker size than number four. He used silk for all ligatures and sutures, except where suppuration was present, when he used catgut. He congratulated Dr. Parsons on his brilliant results, which, however, did not contain any cancer cases and personally he had found that this made all the difference to statistics. Lastly, he thought Dr. Parsons kept his patients in too long. He did not at all agree that a case which died from pneumonia a day or so before she was going to be discharged, after being in the hospital seven weeks, should be included as a death from abdominal section.

Dr. MUNRO KERR read a paper on

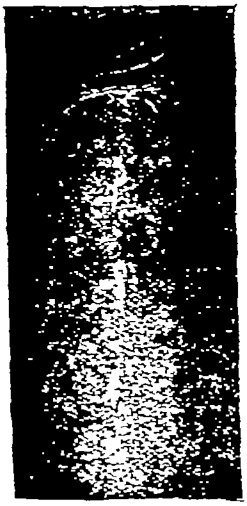
Complete Rupture of the Uterus with Escape of the Fœtus into the Peritoneal Cavity; Panhysterectomy; Recovery.

He detailed a case of complete rupture of the uterus with escape of the fœtus into the peritoneal cavity in which he had performed panhysterectomy with successful result. The uterus had ruptured after a prolonged labour apparently spontaneously. The rupture had not been attended with extreme pain or shock. When the abdomen was opened the full-time child was discovered free in the cavity along with only a very small quantity of blood, liquor amnii, meconium, and vernix caseosa. The child was removed, when the tear involving the right side and front of the lower segment of the uterus was readily seen. The uterine vessels were clamped, the uterus was quickly removed, after which the ligatures were applied to the vessels, and the abdomen washed out. The peritoneum in the lower part was brought together, a gauze drain inserted into the ragged broad ligament, the end being pulled out through the vagina. The abdomen was then closed and an intravenous saline transfusion given. The recovery of the patient was uninterrupted. Dr. Munro Kerr then referred to the symptoms and treatment of ruptured uterus, basing his remarks on the experience of 14 cases. He pointed out that the classical symptoms of profuse bleeding and extreme shock were the origin of which was doubtful. (No. 2559 G, museum of the Royal College of Surgeons of England.)

A woman, aged 24 years, was admitted under my care into St. Thomas's Hospital on Jan. 25th, 1904. She stated that for three and a half years she had suffered from recurring attacks of pain in the right side of her abdomen. These attacks had been of a more severe character of late. During an attack she was feverish, felt sick, and had severe pain in the right iliac region. She had had very numerous attacks of this nature and stated that she had never been free from pain for more than a few hours during the last three weeks. When the appendix was removed it appeared normal, but contained a short dark hair with follicle attached. The following is the description of the specimen in the museum catalogue: "Four minute concretions, in connexion with two of which there is a fine straight hair, the longer of which is ⅜ in. long."

In a third case the hairs were apparently swallowed during the course of the patient's occupation, although the man denied it. They were not human hairs. (See Fig. 6, from the museum of the Royal College of Surgeons of England.)

FIG. 6.



Small fæcal concretions, one of which contained numerous bristles, removed from an inflamed appendix. (From the museum of the Royal College of Surgeons of England.)

A youth, aged 19 years, a photographer's assistant, was admitted on April 13th, 1907. He stated that three years ago he first had pain in the iliac fossa which lasted for about three weeks. About six weeks ago he again had pain in the same part; it came on suddenly and lasted for about three days; it then became better, but the patient kept having attacks of pain for about two and a half weeks; the attacks came on about four or five times a day and lasted for about from half an hour to an hour. He was not sick but suffered from constipation. The pain was always localised to the right iliac fossa. On examination there appeared to be more resistance to pressure than normal, but there was no tenderness. The appendix was found at the operation (on April 17th) to be three and a half inches long, hanging over the pelvic brim. The meso-appendix was very vascular but without adhesions. The lumen was patent and the mucous membrane was catarrhal. Several soft fæcal concretions were present, as was also a considerable amount of soft fæcal matter. There were numerous multi-coloured bristles in one concretion (? camel's hair brush).

In a fourth case there were several minute hairs mixed up in a concretion; they were probably human and might have been bitten off from the back of the hand. The patient, a boy, aged 13 years, had his appendix removed on March 30th, 1906. Six months before he had had an attack of abdominal pain, most severe over the appendix region. He had had other attacks since lasting from seven to ten days. A sort of aching over the appendix region since the first attack which ceased for a day or two and then returned. Seven weeks ago he again had a more severe attack. When apparently better and told to get up the pain returned at once on walking about. Some thickening could be felt in the region of the appendix. The appendix formed part of the wall of an old abscess cavity, retrocæcal, it had a recent catarrh in the upper part and a half-inch concretion in the distal part, its lower pole causing gangrenous ulceration with irregular perforation close to the tip. The concretion was hard and contained a few short hairs. Probably in all these cases the hairs of the stiffer kinds projected beyond the concretions which held them and caused spasmodic attacks of pain as a reflex effect of irritation of the mucous lining of the canal. The lumen of the canal is of such a comparatively small size that the ends of the hairs must have been almost constantly in contact in some part of it.

An Address

ON

THE NATURE AND MANAGEMENT OF HYPERTROPHY OF THE HEART.

Delivered before the Æsculapian Society,

BY ALEXANDER MORISON, M.D. EDIN.,
F.R.C.P. LOND. & EDIN.,
PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL.

GENTLEMEN,—Muscular textures, whether somatic or visceral, if not exhausted and overthrown by too sudden and violent a call upon their reserve power, slowly but certainly endeavour to adapt themselves to fresh demands upon their energy. While this is a general law, it appears to find expression more emphatically in some individuals or organisms than in others. The nutritive powers in some persons—cellular, hæmic, and neural—are greater than in others, if we may judge from the greater hypertrophic increase of over-exercised organs in them as compared with a similar increase under like circumstances in others. The right arm of every village blacksmith does not attain the same size, although one may forge the same number of horseshoes, as his neighbour whose muscular development exceeds his own. Some factor in his nutritional power falls short, or he has come into the world with a smaller amount of the hypertrophiable material. The quantity of such material is fixed in most organs at birth. This fact has a certain interest as it perhaps helps to explain the more easy attainment and maintenance of compensatory hypertrophy in some patients as compared with others. It was shown by my old teacher, Professor Kölliker of Würzburg, that in organs which do not add *new growth* to hypertrophy there is no increase in the number of the elements in an enlarging organ, but an increase in the size of the individual elements. He proved this by the simple process of counting the fibres and noting their individual increase and his contention has never been disproved, although it has been disputed.

This is the great distinction between the increase in size of the cardiac as compared with the uterine muscle. In the latter organ the muscular texture, dealing with a special office of a temporary if recurrent kind, shows an increase in the number of its elements, and the office once performed the new growth returns as we know by involution, that is, by the degeneration and absorption of the added elements, to its original proportions and, presumably, to the original number of its elements.

With all increased exercise of an organ there is an increased blood-flow towards it, and in the arteries of the gravid uterus this increase is manifested by a notable increase in the size of the blood vessels which, as in the case of the other muscular elements, can only be accounted for by an increase in the number of the muscle cells constituting the muscular coat of the vessels.

It has been thought by some that with this actual increase in the number of the organic and vascular muscular elements there is also an increase in the size of the uterine nerves, but there is reason to doubt the correctness of this conclusion in the main as regards the latter. They certainly look larger and are more succulent or swollen in appearance, but there is not sufficient evidence of an increase in the number of the neural elements. It is a point which I investigated with some care in a series of lectures which I delivered in Edinburgh in 1897 and 1898 on the innervation favour of panhysterectomy when operating from the abdomen. In the last seven years he himself had performed the operation of panhysterectomy from the abdomen 85 times with only two deaths, one from embolism on the twelfth day and the other from syncope on the sixth day. He looked upon the operation of supra-vaginal hysterectomy as an operation of the last century.

Dr. WALTER W. H. TATE (London) was interested to find that Professor Strassmann's experience was the same as his own with regard to the occurrence of carcinoma of the uterus with fibroids, that the presence of both in the same uterus was more common than was usually supposed, but he could not agree that the presence of fibroids was a predisposing cause of cancer; he thought that it was much more likely that both diseases had risen independently in the same woman. He thought that if a woman after 50 years of age, who was known to have a fibroid, suffered from bleeding carcinoma should be suspected. He (Dr. Tate) had noticed that the complications of the uterine appendages were very often associated with impacted fibroids, so that he regarded impaction as an indication for removal of the uterus even if it were giving rise to no symptoms. He also agreed that in fibroids complicating pregnancy abortion should never be procured. Either the patient should be allowed to go to term and the condition dealt with then as might seem best or the uterus with its contents should be removed at once.

Dr. WILSON could not see the advantage of the tongue-shaped incision advocated by Professor Strassmann over the T-shaped one. He had yet to be convinced of the advantage of leaving an ovary; he thought that the present teaching was based on mere assertion. There was no proof that could satisfy any scientific and impartial mind that it was better to leave an ovary. With regard to the relationship of carcinoma and fibroid he was sure that there was such a one. In 40 per cent. of his cases of carcinoma of the body fibroids were discovered; in his cases of carcinoma of the cervix only 5 per cent. had fibroids. Perhaps this might be due to the fact that carcinoma of the cervix occurred in younger women than carcinoma of the body; still the very large percentage of fibroids present in his cases of carcinoma of the body made him suspect there was something more than a casual relation between these two diseases. In his own cases of fibroids he had found complications of the uterine appendages in at least 40 per cent. He thought that the pyosalpinges were due to previous infection and not due to the fibroid—at any rate, as a rule. He thought a great danger of pyosalpinx was that it was likely to cause an impaction of the fibroid.

Dr. SWAYNE (Bristol) was in favour of panhysterectomy and not of supra-vaginal hysterectomy.

Mr. MALCOLM in the case of larger fibroids had obtained better results by abdominal removal, and thought that in panhysterectomy the chief point was drainage. He quite agreed with Dr. Wilson that there was no proof that the woman was better for having an ovary left, and he was led to this view by remarking how very well his patients had done in the cases where he had been forced to remove both ovaries.

Dr. MUNRO KERR remarked that the mortality of abdominal hysterectomy had now fallen to between 2 per cent. and 3 per cent., and he would like to know whether Professor Strassmann had found a lower mortality by the vaginal operation.

The PRESIDENT of the section said that he could not imagine why Professor Strassmann should prefer the vaginal operation to the abdominal. The danger of suppuration and hernia had been mentioned, but anyone who had seen Professor Strassmann operate would see that with all the great care he took the former complication would surely be very rare, whereas he did not think there was any risk of hernia with Professor Strassmann's transverse incision. His own mortality for abdominal hysterectomy was very small and the cases he had lost were due to gross neglect of some point of detail, such as infected catgut ligatures. Professor Strassmann had stated that he would not operate on a myomatous uterus without marked reason, or in other words he would leave it alone if it was doing no harm. He could not agree with this. If a patient sought advice with a myoma it was because it was doing harm, and he had found that all patients with fibroids who had consulted him would be better without them. A woman with a fibroid was always in some danger, especially of carcinoma. It had been pointed out that only 2 per cent. of cases were complicated with carcinoma, but the mortality of hysterectomy was now only 2 per cent. He was surprised at Dr. Wilson's remarks about leaving the ovaries, for he could not imagine why a normal ovary should be removed when performing a hysterectomy any more than the woman's nose. If the ovary was healthy why not leave it? and he personally had found that his patients had done much better since he had left their ovaries.

Professor STRASSMANN replied in a very few words and stated that he did not have a higher mortality with vaginal hysterectomy than with abdominal, and that one of his reasons for favouring the vaginal operation was that the patients liked it better; they had no wound to see and there was no risk of hernia. He had had no death after vaginal hysterectomy but had had one after enucleation.

impaired motility in addition. 3. Ulceration with, perhaps, the conditions mentioned in the previous two groups. 4. Lastly, evidence of disease external to the larynx such as glandular enlargement. To differentiate the fundamental changes in the larynx in quite the earlier stages of tuberculosis and malignant disease a minute knowledge of the histology was essential and more particularly of the distribution of the two varieties of epithelium, the columnar and the tessellated, and also of the sites of the transitional epithelium. Dr. Horne had previously demonstrated that the part of the laryngeal mucosa which was richest in glandular structure was most vulnerable to tuberculous infection. He had also shown that that part was covered with columnar epithelium, whereas the part which was clad with squamous epithelium was relatively free from glands and was immune against tuberculous infection, becoming involved only by continuity and at a later stage of the disease. On the other hand, it was commonly accepted that epithelioma was by far the most common form of intrinsic cancer of the larynx. It was also commonly agreed that the ventricular bands and the vocal cords were the more frequent sites of origin of epithelioma. Dr. Horne was in favour of still further restricting this statement to those parts of the ventricular bands and of the vocal cords which were covered with squamous epithelium, and of adding to the statement the sites of transitional epithelium. It therefore followed that it was of the utmost importance as an aid to the differential diagnosis between tuberculosis and cancer to localise the site of origin in the earlier stages which they were then considering. Should the congestion be so diffuse as to involve one entire side of the larynx or both sides, then steps could be taken to blanch it by the application of cocaine and adrenalin. The development of adenoid cancer in the regions reserved for tuberculosis was exceptional and did not invalidate the general application of the principles which he had enunciated. All three diseases, he went on to say, had this in common: they consisted essentially, but in varying degrees, of a cell proliferation and infiltration which burrowed extensively and deeply with the result that as the disease progressed the intrinsic muscles became affected and impaired mobility of one or both cords resulted. It therefore followed that impaired mobility was not peculiar to malignant disease and although an important sign when present it might be absent in quite the earlier stages. It would seem that impaired mobility of a vocal cord was of value as evidence of malignancy in those cases in which the disease presented a well-defined tumour or excrescence, other than pachydermia, and which might be mistaken for an innocent papilloma or new growth. The sign was also of service in cases in which the origin of the growth was so deep-seated that fixation of the cord was the only clinical feature observable in the larynx above the level of the glottis. Passing to the second group—the stage of tumefaction or of a definite tumour or excrescence—he said that the situation of the tumour would assist in excluding or admitting tuberculous disease into the diagnosis, unless the tumour happened to be situated at a site of transitional epithelium such as the vocal process, as was the case in pachydermia laryngis. Dr. Horne referred to a paper which he read at the Portsmouth meeting of the Association in 1899 to show that pachydermia laryngis should be regarded more as evidence of disease than as a disease in itself. It might be occasioned by syphilis, or tubercle, or cancer of the larynx, and even the variety which might claim to be called simplex was not uncommonly associated with fibrotic disease in other organs. It therefore followed that a diagnosis of pachydermia was not sufficient in itself. They had to be prepared to exclude the causation of the pachydermia. In illustration of this point Dr. Horne referred to the case of the late Emperor of Germany. Passing to the third group of cases in which the tumefaction had broken down and there was ulceration, he reminded them that they would be considerably assisted in excluding tuberculosis by the pathological fact which he had demonstrated elsewhere—namely, that when tuberculous disease in the larynx presented ulceration that in the lungs had already reached cavitation; further, that primary tuberculosis of the larynx was a negligible quantity. Dr. Horne briefly referred to other forms of ulceration of the larynx which might simulate malignant disease and cited a case in which extensive ulceration along one-half of the larynx had been the site of infection in a case of infective endocarditis. Passing to the fourth and last group, in which there was external evidence of laryngeal disease such as glandular enlargement, he said this might appear to be in itself presumptive evidence of the disease in the larynx being of a malignant nature. It did not, however, exclude the possibility of it being tuberculous. Before eliminating tuberculosis in a differential diagnosis he mentioned that cases had been recorded in which tubercle and cancer had occurred in the same larynx. Assuming that tuberculosis had been eliminated in the manner indicated from the diagnosis, the problem then resolved itself into a diagnosis between syphilis and cancer. Tuberculosis having been excluded, large doses of iodide of potassium might then be pushed without doing the patient harm, and assuming that the condition in the larynx cleared up, as it generally did if it was purely syphilitic, then the diagnosis might be allowed to rest with that of syphilis, more particularly if there was a strong history in support of it, but needless to add, such a history would not exclude the possibility of syphilis being only a factor in the case and not the important part of the disease. In connexion with cancer Dr. Horne described a method of transillumination of the larynx as an aid in differential diagnosis. In his concluding remarks he referred to the all importance of a laryngoscopic examination and of that examination being made at the earliest possible moment. They had been discussing the most dreaded diseases of the larynx, diseases all amenable to local arrest, if not to cure, when detected early, but all three diseases were so insidious in their onset that they would seem to have no beginning, and yet so progressive in their character that an early examination afforded the only hope of saving the larynx from becoming a most veritable citadel of misery.

Dr. N. C. HARING (Manchester) attached importance to fixation of the cord as evidence of malignancy. In secondary syphilis the anterior part of the cord usually showed more congestion than in tuberculosis or cancer. The damage done to the larynx in some cases of enteric fever at times presented appearances which were difficult to explain apart from the history of the case. In tuberculous ulceration of the posterior part of the larynx the lungs were less extensively affected.

Mr. HERBERT TILLEY (London) cited a case of tuberculosis which clinically so closely resembled cancer that an exploratory thyrotomy was performed before the diagnosis was cleared up.

Dr. J. DUNDAS GRANT (London) considered that the unilaterality of congestion was of service as an aid in the diagnosis only in the very earliest stages of tuberculosis. He referred to a roughness associated with redness of the vocal cord met with in tubercle and differing from the beefy redness seen in simple laryngitis. In secondary syphilis the redness was quite indistinguishable unless mucous patches were present.

Dr. G. WILLIAM HILL (London) spoke in favour of the clinical procedure indicated by Dr. Horne. Animal experiments necessitated a loss of what was often valuable time.

Dr. B. H. SCANES SPICER (London) considered that Dr. Horne had put before them the method of the future for making a differential diagnosis. He considered that extrinsic malignant disease was more frequent than commonly stated and that hospital statistics would support this view, using the term extrinsic to include those cases originating within the larynx and extending beyond as well as those strictly extrinsic in origin.

Dr. H. S. BIRKETT (Montreal) mentioned that tuberculin had been found of the greatest value in America, especially in the diagnosis of those cases which presented only localised hyperæmia of one cord and without any signs in the chest.

Dr. W. S. SYME (Glasgow) pointed out that in the early stages of syphilis the tint of the laryngeal mucosa was more purple, whereas in the early stages of tuberculosis it presented rather a pinkish colour.

Dr. ADOLPH BRONNER (Bradford) spoke of a diffuse fibroma of the vocal cord occurring in old people which at times presented a difficulty in diagnosis. The tuberculin test was liable to be followed by œdema necessitating tracheotomy, and it was as well to be prepared for this contingency and to have the patient under observation.

Dr. J. B. BALL (London) spoke in favour of iodide of potassium for diagnostic purposes, and speaking on the general question he considered that there were some cases in which syphilis, and others in which tubercle, would have to be excluded first.

cancer of the bile-ducts may be of a similar nature the possibility of such an occurrence has to be borne in mind in making a diagnosis of pancreatitis.

The examination of the urine, fæces, and stomach contents in this case suggested obstruction of the common duct with secondary chronic pancreatitis, and the histological examination afforded abundant evidence of the correctness of these conclusions, thus once again demonstrating the usefulness of these methods when carefully and correctly carried out. The inference as to the simple nature of the cause of the obstruction was, however, proved to be incorrect, but the condition was so anomalous and outside our previous experience that a correct conclusion was practically impossible.

An examination of the stomach contents for free and physiologically active hydrochloric acid has proved of assistance in two cases of malignant disease of the head of the pancreas, but in this instance the results of this examination were misleading, as they had been in the cases of growth of the common duct previously mentioned. We are therefore of opinion that while the absence of free and physiologically active hydrochloric acid may afford useful confirmatory evidence in suspected cases of cancer of the head of the pancreas, their presence, even in considerable amount, is not of any diagnostic value, especially when the growth is situated in the common duct or gall-bladder.

The case is clinically interesting as showing how closely cancer of the gall-bladder may simulate cholelithiasis, if the disease be associated with suppuration. The intermittency and severity of the attacks of pain for 13 months, without jaundice, suggested the presence of gall-stones in the cystic duct, and the last severe seizure, followed by jaundice, made it appear probable that a calculus had passed into the common duct. Although no gall-stones were actually found, either at the operation or later, it is quite possible that cholelithiasis may have been the original cause of the disease, and this is rendered probable by the presence of more advanced inflammatory changes in the head of the pancreas than could be accounted for by the recent invasion of the gland by malignant disease from the duct of Wirsung. The nodular character of the growth felt before operation and the reported loss of flesh and strength led to a suspicion of cancer, but the well-marked signs of suppuration gave the impression that some relief, and possibly something more than relief, might be given by the evacuation of the abscess.

On several occasions it has been the good fortune of one of us to operate under similar circumstances and to find the disease to be simple, the operation leading to complete and perfect recovery, but in this case it became at once apparent on opening the abdomen that merely temporary relief was all that could be hoped for.

Our experience in other cases of cancer of the pancreas has shown that an inflammatory condition is apt to supervene as a complication in a certain proportion of cases, and unless this is borne in mind it may lead to errors in diagnosis and to useless operation, for it must be acknowledged by all who have had experience of such cases that primary cancer of the pancreas is a hopeless disease however it may be treated.

CALCULI IN THE APPENDIX.[1]

BY D. T. BARRY, M.D. R U.I., F.R.C.S. ENG., D.P.H.,
DEMONSTRATOR OF PHYSIOLOGY IN QUEEN'S COLLEGE, CORK.

BEING at present engaged with Professor J. J. Charles in a little research work on the structure of the appendix my attention was directed to the subject of calculi and other bodies found in this organ by finding four small stones in one of the specimens submitted to me by Dr. D. P. Fitzgerald, our assiduous demonstrator of anatomy.

There seems to be no definite understanding as to the exact nature of these bodies, but that they are not always of the same kind is certain. Before attempting a classification I will give the results of a rough analysis of those specimens and a few extracts from recent literature on the subject. The appendix in this case was somewhat fusiform in shape, having a bulging middle and contracted ends. Microscopically the distal end for quite half an inch from the tip presented no lumen and no trace of glands or of lymphoid tissue. Between this and the distended site of the calculi a portion intervened containing a plug of mucus in the lumen, a fairly regular set of glands, and showing some inflammatory changes. The distended portion showed atrophy of the mucous membrane and thinning of the muscular coat. The proximal end contained a plug of mucus. The calculi were four in number, each about two millimetres in diameter, dark brown in colour, smooth, and facetted. Allowed to fall on a plate they gave a ringing sound in no way differing from that given by a small gravel pebble of the same size. While engaged in this latter pastime I lost one of the precious stones.

The next step in the examination was to macerate one with a dilute solution of sulphuric acid and to test the surface layer microscopically and chemically for cholesterin. These tests were negative. Gmelin's test for bile pigments and Pettenkofer's test for bile salts also gave negative results. Further examination showed that the stones were composed chiefly of calcium phosphate with a small amount of organic matter.

To quote briefly from a few recent investigators:—

Howard Kelly[2] states: "Gall-stones, also, which formerly were supposed to enter the appendix frequently are exceedingly rare; but they are often so closely simulated by enteroliths that a chemical analysis is necessary for their exclusion. The clinical evidence in some of these cases so strongly supports the gall-stone theory as to leave no doubt in the mind of the observer." McAdam Eccles[3] maintains that calculi in the appendix are always enteroliths and always formed *in situ*. Walsham and Spencer[4] state: "The appendix may contain true fæcal concretions or coprolites. Enteroliths proper where the fæcal constituents and inspissated mucus are mixed with calcareous material derived from the inflamed wall, like tonsillar concretions and rhinoliths, are more rare, while foreign bodies, such as fruit-stones, &c., are still rarer." Roberts[5] remarks: "They [gall-stones] cause trouble by lodging in the vermiform appendix.' Lediard of the Cumberland Infirmary recently writing in THE LANCET describes a case on which he operated. The patient showed the usual signs of an acute appendicitis and there was no previous history of gall-stones or a symptom pointing to them. In the appendix were found 11 small black stones, and they were found to consist of cholesterin and bile pigments. Murchison[6] expresses strong doubt of the presence of gall-stones. Osler,[7] in reference to gall-stones in the intestine, remarks: "Courvoisier's statistics give a total of 131 cases, in six of which the calculi had a peculiar situation as in a diverticulum or the appendix." He also states: "The lumen of the appendix may contain a mould of fæces. Concretions, enteroliths, coproliths are also common."[8]

It is only by numerous analyses with careful reports of the separate cases met with that we can allay the uncertainty prevailing in connexion with this subject. It is important to arrive at some conclusion as to the different types of bodies found with the relative frequency of each. It will be seen from the above quotations that there is a confusion of terms. One concludes, for instance, that concretions, fæcal moulds, enteroliths, and coproliths are all distinct things, while in addition the terms stercolith and coprolite are used. Would it not be well to use the term fæcal mould for those masses of inspissated fæces somewhat resembling a date-stone in appearance and containing the usual percentage of inorganic matter found in fæces? The term "enterolith" might well be employed for other forms where the inorganic material preponderates.

To my mind, a very important consideration in these cases is the condition of the appendix itself. If gall-stones migrate from main gut to appendix we should expect to find, according to the size and number of the stones, a patent lumen with more or less destruction of the mucous membrane over which the stone has passed. The case reported by Lediard,[9] where 11 gall-stones seem to have thus migrated one after the other, must surely have presented some interesting features in structure to which no reference is made. The case here reported by me showed changes exactly corresponding to formation *in situ* and to formation as a result of increased inorganic matter accompanying inflammation.

In conclusion, I would express an opinion that, excluding

Mr. **CHICHELE NOURSE** read a paper entitled "Observations on Frontal Sinusitis."

This concluded the day's proceedings.

FRIDAY, AUGUST 2ND.

Mr. **THOMAS GUTHRIE** (Liverpool) demonstrated a series of drawings illustrating

The Development of the Middle Ear, with Special Reference to the Origin of the Mastoid Antrum.

The drawings were made from microscopical specimens of fœtal temporal bones of ages ranging from two and a half to seven and a half months of fœtal life. Serial sections were cut of the temporal bones, the plane of section corresponding as nearly as possible with that of the tegmen tympani. Mr. Guthrie considered that the drawings bore out the statement of Professor Young and Dr. Milligan[1] that the antrum was essentially a part of the middle-ear cleft and was not formed as a diverticulum of the tympanum. He thought that the drawings showed also that in the early stages of development the antrum, although present, was relatively of véry small size as compared with the tympanic and Eustachian portions of the middle ear cleft. During the greater part of fœtal life the antrum was in no way marked off from the rest of the cleft and was indeed nothing more than the small angular recess with which the middle-ear cleft terminated posteriorly. The walls of the recess were formed by the squama externally and the periotic internally, while it was closed behind by the apposition of these bones. The drawings showed the gradual increase in size of this recess and made it clear that its growth was relatively very great as compared with that of the tympanic portion of the middle-ear cleft, so that at birth the antrum was of large size and marked off from the remainder of the cleft by a definite aditus. Mr. Guthrie wished to express his thanks to Professor Patterson of Liverpool for providing the material for this work, a great part of which was done in his laboratory.

Dr. **EUGENE S YONGE** (Manchester) read a paper entitled

"*Observations on the Determining Cause of the Formation of Nasal Polypi.*"

Dr. Yonge said it was generally considered at the present time that a mucous polypus of the nose was, essentially and in its earliest stage, a patch of mucous membrane which had become œdematous, and that the pedunculated appearance which a polypus commonly assumed was a character not peculiar to itself but shared with many other intra-nasal swellings and new formations, and chiefly referable to known physical causes acting on the primary patch of swollen, œdematous mucosa. The question of etiology centred, therefore, on the determining cause of the initial œdema, and of this process a number of explanations, unfortunately more or less incomplete, had been advanced. His investigations (of which a full account had been published in a recent monograph[2]) had led him to the conclusion that the localised œdema of the mucous membrane, which represented the first stage of polypus formation, was a serous infiltration of the tissues, the result of obstruction of the efferent circulation of the part; that the particular vessels which became obstructed were the periglandular capillaries and veins; and that the circumstance which caused the obstruction was the distension or cystic dilatation of the mucous glands—more particularly the gland ducts. The contention that dilatation of the mucous glands was the determining cause of polypus formation, by leading to the localised œdema which initiated the process, was supported by evidence derived from pathological, experimental, and clinical observations which Dr. Yonge detailed.

Dr. **WATSON WILLIAMS** could not agree with the theories put forward by Dr. Yonge. Reflex neuroses, he considered, very frequently but not always were due to pathological changes, perhaps unrecognised and unrecognisable, but previously established. Polypi were never due to the vascular changes associated with a pure neurosis. They were the outcome of obstruction in the lymphatic vessels in a restricted area of the involved mucosa, an inflammatory change resulting from infection; in a word, an infective lymphangitis with blocking of the vessels analogous to elephantiasis. If the obstruction were temporary the œdema might disappear; if permanent a polypus formed and continued to grow, being fully supplied with blood; indeed, polypi were usually highly vascular structures. In course of time various hypertrophic changes, due to the excessive lymph supply, took place in a polypus.

Dr. **SOANES SPICER**, Mr. **STUART-LOW**, and Dr. **BRONNER** continued the discussion.

Dr. **BALL** considered that there were three forerunners of nasal polypi—namely, catarrhal conditions, paroxysmal sneezing, accessory sinus suppuration, and that cases could be placed in one or other of these three classes.

Dr. **MILLIGAN** said that Dr. Yonge's monograph was not convincing. He (Dr. Milligan) desired to associate himself with Dr. Watson Williams and the lymphatic theory, and inquired if Dr. Yonge's theory that polypi were due to an irritant were correct why was it that polypi were never found in snufftakers.

Dr. **WHITEHEAD** could not fully accept Dr. Yonge's paper. Dr. Whitehead considered that there must be some definite abnormality in the nose, and he believed in the hereditary factor. The infective theory did not explain the occurrence of a single and very large polypus.

The **PRESIDENT** of the section considered that the views put forward by Dr. Watson Williams were applicable to a large number of cases. The President pointed out that it was not easy to examine cats' noses during life, and it was important to know the clinical condition of the cat as well as the pathological condition met with after death, and on that account the experiments reported by Dr. Yonge were not completely satisfactory.

Dr. **YONGE**, in reply to a question by the President, stated that the irritant used in these experiments was olive oil with oil of mustard to set up an inflammatory process and for the purpose of bringing about a distension of the glands the animal was placed in a chamber with pepper on the floor.

Mr. **GEORGE JACKSON** read a paper entitled

The Relative Frequency of Caries of the Superior and Middle Turbinates and Ethmoid Bones, and the Importance of Examining the Nose in all Cases with Symptoms of Deafness, Giddiness and Vertigo, and Throat Affections, with some Remarks on the Treatment thereof.

He stated that whilst he had nothing new to bring forward he was desirous of drawing attention to a condition which was frequently overlooked—namely, ethmoidal disease. Although he was not in favour of the term "necrosing ethmoiditis" he could substantially endorse the work done by Dr. E. Woakes. He referred to his own clinical experience in which he found that of all cases of middle-ear disease upwards of 50 per cent. had some evidence of disease in the ethmoidal region.

Dr. **SCANES SPICER** applauded the work done by Dr. Woakes and advocated the treatment of nasal conditions in cases of tinnitus and other aural symptoms.

Dr. **BRONNER**, whilst also applauding the work done by Dr. Woakes, considered that the data could not be so fully accepted in the light of more recent work.

Dr. **WATSON WILLIAMS** gave a demonstration, with stereoscopic lantern slides, on

Some Points in the Anatomy and Surgical Treatment of Nasal Accessory Sinus Disease.

He showed, amongst others, illustrations of operations on the frontal sinus as practised by Killian of Freiburg and Delsaux of Brussels, and also illustrations of a method he had himself adopted.

Dr. **MILLIGAN** gave a lantern demonstration on

The Surgical Treatment of Labyrinthine Suppuration.

Dr. **BRONNER** read the notes of a case of

Thrombosis of the Lateral Sinus with Complete Obliteration of the Jugular Vein.

Dr. **ARTHUR HAYDON** (London) gave some illustrations of

The Effects Produced by the Singing Voice in a Suitable Medium.

The proceedings closed with a most cordial vote of thanks to the President of the section which was proposed by Mr. **CRESSWELL BABER** and seconded by Mr. **SOANES SPICER** and carried unanimously.

OPHTHALMOLOGY.

THURSDAY, AUGUST 1ST.

Mr. **F. RICHARDSON CROSS** (Bristol) opened a discussion on

* No physician can certify that the boy *can* run, although he may sometimes be able to say that he *cannot*.

As soon as it is clear to the captain in charge that the boy can run well, the sooner he is promoted to the next longer run the better for his welfare in every respect.

N.B.—Appropriate space is required to insert the details of the examination.

The record commenced on Jan. 21st, 1899, and was completed on May 6th, 1907. I have begun to tabulate a second thousand entries, which I hope will be similarly concluded by other hands than mine.

Height, Weight, and Chest Measurements.

It would be of considerable interest were I able to record the *annual* rate of growth in height, weight, and chest measurements, inasmuch as boys vary greatly in this respect, for some grow slowly before puberty, but make up for this defect at the age of puberty, or even postpone this increase until the ages of 17 or 18, when they grow enormously. In fact, many boys who develop very gradually at first, both mentally and bodily, outstrip their schoolfellows in both respects towards the end of school-life—some growing in height at the expense of weight, and *vice versâ*.

The tables which I have used are those of Mr. Charles Roberts, who is the only author who has recorded, amongst others, the height and weight of public school boys. His table is here appended:—

Table showing the Average and Mean Height and Weight and the Annual Rate of Increase of 7709 Boys and Men, between the Ages of 10 and 30 Years, of the Most Favoured Classes of the English Population—Public-school Boys, Naval and Military Cadets, Medical and University Students.

Age last birthday.	Height without shoes.				Weight, including clothes of 9 lb.			
	Average.	Growth.	Mean.	Growth.	Average.	Growth.	Mean.	Growth.
	Inches.	Inches.	Inches.	Inches.	lb.	lb.	lb.	lb.
10	53·40	—	53·00	—	67·4	—	67·0	—
11	54·91	1·51	54·50	1·50	72·9	5·50	73·0	6·0
12	56·97	2·06	56·50	2·00	80·3	7·39	80·0	7·0
13	58·79	1·82	58·50	2·00	88·6	8·27	88·0	8·0
14	61·11	2·32	61·00	2·50	99·2	10·61	98·0	10·0
15	63·47	2·36	63·50	2·50	110·4	11·21	110·0	12·0
16	66·40	2·93	66·50	3·00	128·3	17·92	126·0	16·0
17	67·84	1·46	68·00	1·50	141·0	12·69	140·0	14·0
18	68·29	0·43	68·50	0·50	146·0	4·97	146·0	6·0
19	68·72	0·43	68·75	0·25	148·3	2·20	148·0	2·0
20	69·13	0·41	69·00	0·25	152·0	3·67	150·0	2·0
21	69·16	0·03	—	—	152·3	0·27	152·0	2·0
22	68·93	—	—	—	154·7	2·44	—	—
23	68·53	—	—	—	151·7	—	—	—
24	68·95	—	—	—	149·2	—	—	—
25–30	69·06	—	69·00	—	155·2	0·42	154·0	2·0

The record of the height, weight, and girth is of inestimable value to the master who, possessing this chart, on which are also prescribed the suitable physical training and games for every "new boy" admitted, is thus intelligently and efficiently enabled to provide for his appropriate individual rearing during the period of education. At some future date these registers of height, weight, and girth should be subjected to minute analysis and classification, for they contain indiscriminately the cases of boys of excessive height with defective weight and of diminished growth with abnormal weight. This necessary analysis, however, must be undertaken by others who have more leisure at their disposal than I can command, as well as greater ingenuity in the handling of figures. The circumference of the chest, measured on the bare skin at the nipple-line, expresses the capacity of the lungs on deep inspiration and expiration. This respiratory capacity has a wide range, varying from one inch to five inches.

In specifying the numbers throughout this paper it must be recollected for the purpose of avoiding continuous repetition that they are all in relation to the standard of 1000.

Height	Above normal	522
	Average	113
	Below normal	365
Weight	Above normal	472
	Average	57
	Below normal	471
Chest measurement	Above normal	445
	Average	132
	Below normal	423

Deformities.

It is necessary to state *in limine* that in no instance were slight defects registered, but only such as were of sufficient practical importance to the sufferer to need special attention form where there was no refractive error or defect in visual acuity but where the fusion faculty was totally absent. In these latter neither glasses nor operation would produce a cure. Javal, on the other hand, stated that where there was time and the patient was intelligent binocular vision could be restored by operation. He had treated some nine cases where true alternating squint had appeared, and were certainly not variants of monolateral squints, by Javal's method with the best of results. In all these cases glasses had been prescribed and discarded since they did not correct the squint. Good vision was maintained, although the squint had been established in some cases from an early age until the age of 18 years. He practised advancement of the external rectus with tenotomy of the internal rectus, according to the degree of correction required. So far his results had been uniformly good. The eyes looked straight and, what was more important, they maintained concurrent visual axes, for diplopia was noticed if binocular fixation fell off. He secured binocular vision of a quality to obtain fusion of stereoscopic pictures. He thought that when alternating squints were permanent the best course was at once to correct the deformity by operation and then to proceed to show the patient by the amblyoscope or stereoscope what binocular vision was and to try to produce the irritation of diplopia, then fusion was very near. The best age for this was from 12 to 16 years; then a child was keen enough on learning to attend to stereoscopic pictures.

Dr. P. W. **MAXWELL** (Dublin) agreed that alternating squints yielded better results from treatment than did fixed squints. Operation was particularly indicated in alternating divergent squints.

Mr. E. E. **SMITH** (Hyde) and Dr. A. **HILL GRIFFITH** (Manchester) communicated an account of

A Fatal Case of Orbital Thrombosis.

The patient was a man, aged 25 years, a roofmaker; after some exposure on a roof he felt pain in the eyes and had epistaxis. There were throbbing and swelling about the eyes and he could not sleep. On the fourth day the pain in the head was severe and the patient's manner was rambling; the left eye was prominent and the lids and conjunctiva were swollen. The man had suffered from discharge from the ear in childhood; the ear was examined and a scar of the drum was found; there were slight tenderness and œdema about the mastoid, probably caused by a mustard poultice. There was hypertrophy of the middle turbinate bone of the left side, but no discharge. The fundus of the eye was normal. The urine was normal. On the fifth day the left eye became more prominent and the right eye began to be pushed forwards, the pain and delirium increased, Cheyne-Stokes breathing and drowsiness set in, and on the seventh day the man was comatose and died in the night. A diagnosis of orbital and sinus thrombosis had been made on the protrusion of the eyeballs. This bulging subsided immediately after death. A post-mortem examination was not permitted, but in a similar case[1] diagnosis had been confirmed by the finding of a complete orbital and sinus thrombosis without other cranial lesion or middle ear disease.

Mr. **PARSONS** said that Mr. Percy Fleming had had several such cases at University College Hospital. There was no distension of the retinal veins, probably because the anastomosis was so complete. Usually paresis of the sixth nerve of the opposite side was the earliest indication of the spread of the thrombus.

Dr. **JAMES HINSHELWOOD** (Glasgow) read a paper on

Four Cases of Congenital Word Blindness in One Family.

Kussmaul in 1877 described an acquired aphasia wherein there was a "complete text-blindness, although the power of sight, intellect, and speech were intact." The patient saw words but could not read them. Pringle Morgan[2] first recorded a case of the congenital form.

Dr. C. J. **THOMAS** of the London County Council Medical Department (Education) called attention to the fact that the condition often affected several members of a family and might be hereditary. The cases he should describe were examples of this last type. Of 11 children of one family the eighth to eleventh could not learn to read. Although they were otherwise intelligent, in some of them their capacity in arithmetic was particularly good. One at the age of 18 years had become a football enthusiast and by much exertion he had learned to recognise many of the terms used in the sport, so that he could read them at sight, although he had the greatest difficulty in recognising short monosyllabic words in a child's primer. This case showed that the difficulty in learning could be overcome by persistent and persevering attention. It also suggested that individual teaching was required.

Mr. W. T. **HOLMES SPICER** (London) thought that cases of word-blindness might be overlooked when associated with errors of refraction. He had recently a case of this kind under his care; there was a high degree of mixed astigmatism, but the correction of this did not improve the capacity for reading, although the intelligence of the child was good.

Mr. J. **ELLIOT SQUARE** (Plymouth) detailed the case of a man who could never learn to read but yet was perfect in money matters, paying bills and obtaining change with accuracy.

Mr. **STEPHENSON** had seen a case of four affected in one family—three girls and one boy.

Mr. **CYRIL H. WALKER** (Bristol) remarked that in all these cases the disability seemed to be of about the same degree. There were no slight cases.

FRIDAY, AUGUST 2ND.

Mr. **SPICER** opened a discussion on

Vesicular Affections of the Cornea.

He said that the corneal epithelium was soft and delicate, exposed to injury and to dryness from evaporation, received nutrition through very indirect channels, and was only loosely attached to Bowman's membrane. It retained its clearness and health to old age, probably owing to the perfection of its sensitiveness. Sensation in the cornea, unlike that in the skin, was simple only and gave a pain reaction only to all harmful stimuli. The epithelium was easily detached in one or more of its layers or as a whole from Bowman's membrane. In reptiles which cast off their epidermis periodically the epithelium of the cornea was cast off too, and the periodic detachment of the epithelium in relapsing bullous keratitis might be a tissue memory of the time when periodic shedding of the surface was normal. Casting off of the epithelium as a whole was seen in various acute diseases, in panophthalmitis, purulent conjunctivitis, keratomalacia, neuro-paralytic keratitis, and others, and also after the use of cocaine and various drugs. Local detachments were also commonly met with Examples were given of both general and partial exfoliations. The protective mechanism acted in two ways: by the pain which interference with the surface brought and by the influence which the healthy nerve had on nutrition, or its trophic influence. In normal eyes wide differences existed in the corneal pain reflex in individuals; where ulcers were found the pain reflex was often deficient; in one eye in which an ulcer was present with defective reflex the other eye frequently had a defective pain reflex too: such eyes were especially liable to suffer from ulcers. Partial or local defects of sensation in the cornea also occurred, leading to localised epithelial diseases. In herpes zoster of the fifth nerve there was a disease of the Gasserian ganglion leading to anæsthesia of the cornea and hence to liability to injury. In some cases instead of surface affections deep or interstitial keratitis, iritis, cyclitis, and diminished tension occurred—that was, in addition to the anæsthesia, some influence of an irritative kind or a cessation of normal influences passed outwards along the nerves leading to deep changes within the eye. If this were true of the main trunk of the ophthalmic nerve it might also be true of the smaller terminal branches; an inflammation of the nerve itself might set up irritation at its periphery. Some influence of this kind was probable because of the peculiar behaviour of some nerves of this group, among which were included febrile herpes, dendritic ulcers in their various forms, and filamentary keratitis. Febrile herpes in the skin was well known; it occurred about the lips, the eyelids, and other parts of the face; sometimes in facial attacks vesicles appeared on the cornea and sometimes they affected the cornea without the face. Examples were given of these associated affections, and a case was detailed where a man suffered an attack of acute herpes consequent on a dendritic ulcer of the cornea. Filamentary keratitis was considered to be a variety of the herpetic form, the filaments being formed by the twisting into a rope of shreds of torn bullæ by the action of the lids. Dendritic ulcers were of raised pink spots scattered over the trunk, and tenderness was present in the right iliac fossa. Within 24 hours of admission, the arm being sterilised as for operation, ten cubic centimetres of blood were withdrawn from the median basilic vein and immediately inoculated into three 100 cubic centimetre flasks of broth in as equal quantities as possible, then incubated at 37° C. for 24 hours. A pure growth of a motile bacillus was obtained in each flask, which, when subcultured on agar streak and plates, appeared to be a typical growth of bacillus typhosus abdominalis and was verified by further inoculation. At the same time blood for a Widal reaction was sent into Edinburgh, the report being positive. A point of interest is that one of the blood smears made from the ear that day and stained with Jenner showed a few scattered bacilli in all five fields, usually two bacilli together, varying in size, and individual bacilli staining feebly. Although many more smears were made on subsequent days I was not again fortunate enough to find bacilli, which probably were present. The white blood corpuscles never rose above 8000, the differential count showing a slight increase of the polynuclear leucocytes. The fever ran a normal but very severe course and the patient made an uninterrupted physical and mental recovery.

---

[1] A. Hill Griffith: Ophthalmic Review, vol. iii.

[2] Brit. Med. Jour., November, 1896.

I use the same methods for bacteriological examination of the blood in all acute insanities and on three occasions I have found bacilli in the smears from the peripheral blood of general paralytics during a congestive seizure.

I am indebted to Dr. George M. Robertson, superintendent, for permission to publish this case and to Dr. C. H. G. Gostwyck, medical officer, for clinical notes.

Larbert.

Reviews and Notices of Books.

A Text-book of Diseases of Women. By CHARLES B. PENROSE, M.D., Ph.D., formerly Professor of Gynæcology in the University of Pennsylvania. With 225 Illustrations. Fifth edition, revised. London and Philadelphia: W. B. Saunders Company. 1907. Pp 550. Price 16*s.* net.

Professor Penrose has written this work for the student. He has therefore in most instances recommended only one plan of treatment and has omitted all facts of anatomy, physiology, and pathology which can be found in the general text-books on these subjects. The result is that he has been able to present all the essential facts of gynæcology within a comparatively small compass. The book is arranged on an anatomical basis, the diseases of the different regions of the generative organs being considered in order. The descriptions are of necessity concise, and indeed in some instances perhaps the author errs on the side of omission. Thus we find only one variety of cyst of the vagina alluded to and that one not the most common—viz., the one derived from the duct of Gartner. Injuries to the perineum are fully dealt with and Emmet's operation is well described and illustrated. The chapter on the Normal Position of the Uterus and its Supports is an excellent one and forms a good introduction to those which follow, dealing with the important conditions of prolapse and displacements of the uterus. The teaching as regards anteflexion agrees with that usually found in English text-books—namely, that it is of no importance by *itself*, and that the symptoms at times accompanying it require treatment, not the displacement. Some interesting statistics are given of the after-results of the operation of ventro-suspension of the uterus. Out of 310 cases operated upon by the author or his assistants the results in 211 are as follows. In 131 cases the symptoms for which treatment was sought were relieved, in 49 cases improvement followed, while in 31 cases there was no improvement. 20 women became pregnant, and all of these went to full term and the children were all born alive. In 18 of the cases the labours were normal, in one forceps were applied, and in one labour was prolonged and difficult, although instruments were not used. In eight cases miscarriage occurred, not an abnormal proportion out of 211 patients.

An interesting account is given of the rare condition of congenital erosion and split of the cervix. We notice that the author employs the ugly word "placentoma" as synonymous with deciduoma malignum. In considering the treatment of fibroid tumours the conclusion is come to that the great majority of these growths demand immediate operation. The writer remarks that no drug has been discovered which has any influence on the growth of these tumours. In discussing the treatment of inversion of the uterus some mention might have been made of the various operations apart from hysterectomy which have been devised for the treatment of those cases which cannot be dealt with by instrumental re-position. The advice which is given with regard to the operative treatment of cases of tubal disease is good and the dangers of the various conservative measures which are so strongly urged by many writers are pointed out clearly. That tuberculosis of the tubes is a fairly frequent affection is shown by the figures given by the author who has met with this condition in no less than 18 per cent. of the cases operated upon for inflammatory diseases of the uterine appendages. Recent observations have shown that cysts of the corpora lutea are not so rare as is stated in the chapter on Cystic Tumours of the Ovary. It is true that they rarely attain any very large size and are therefore more interesting from the pathological than from the clinical point of view. The great importance of gonorrhœa as an etiological factor in diseases of women is indicated by the fact that a chapter is specially devoted to a discussion of this affection. Professor Penrose is careful to point out how easily the importance of the gonococcus may be overrated and how difficult it often is to prove with certainty that any particular patient has really had an attack of gonorrhœa perhaps some years before she comes under observation, and the careful physician will therefore be loath to make such a diagnosis unless he has good grounds for doing so. It is an undoubted fact that many men who suffer from gonorrhœa before marriage become completely cured and never infect their wives.

The last five chapters of the book are devoted to the technique of gynæcological operations, the after-treatment of patients operated upon, and the effects of the removal of the uterine appendages. The author is to be congratulated upon his success in presenting the main facts of the diseases of women in a work of moderate size and in so clear and lucid a manner. The book should well fulfil the purpose for which it is written and it is a more trustworthy guide than many works of greater pretentions.

Opuscula Selecta Neerlandicorum de Arte Medica. (*Selected Memoirs and Addresses on Medical Subjects, by Dutch Authors.*) Amsterdam: F. van Rossen. 1907. Pp. 325.

HOLLAND has at all times been well represented in the world of literature and science, but for the general reader the nationality of many Dutch authors is obscured by the fact that at one time they wrote in Latin with their names latinised, and at a later period many of them wrote in French or German with a view to reaching a larger public than that of their own country. A modern tribute to some of the great names of old has been paid by a leading Dutch medical journal, the *Nederlandsch Tijdschrift voor Geneeskunde*, which has celebrated the fiftieth anniversary of its first appearance by publishing the handsome volume now before us. Out of the large amount of material at its disposal the committee appointed by this journal selected six articles by the following authors: Desiderius Erasmus of Rotterdam (in Latin); Antoni van Leeuwenhoek of Delft (in Dutch); Jan Swammerdam (in Dutch); Hermann Boerhaave of Leyden (in Latin); Jerome David Gaubius of Leyden (in Latin); and F. C. Donders of

THOMSON HENDERSON (Nottingham) read a paper on

The Pathogenesis of Glaucoma and the Rationale of its Treatment.

He believed the underlying predisposition to glaucoma existed in alteration of the pectinate ligament. Sclerosis of the fibrous tissue of the structure diminished the permeability of the channels and ultimately obstruction. The sclerosis was natural to all eyes but exaggerated in hypermetropia owing to the continued traction of the ciliary muscles. Features of importance were, the absorbent powers of the iris which was not to be looked upon merely as a light diaphragm; and the quality of the aqueous which was not a true secretion but an exudate dependent on arterial blood pressure. There was a fine balance between the production of aqueous and its absorption by the iris and escape through the pectinate ligament. Excitement increased the first; dilatation of the pupil closed the crypts of the iris and diminished the second; whilst the sclerosis of age prevented the third. When aqueous production was excessive and venous return was difficult, the iris became swollen, œdematous, and congested; and it was then that its root became applied to the pectinate ligament and glaucoma ensued. He looked upon acute glaucoma as essentially depending upon an acute iritic œdema for its determination. In chronic glaucoma he thought the iris never became adherent to the filtration angle, but that the slow increase of tension was consequent on the steadily advancing sclerosis of the pectinate ligament. Buphthalmos arose from failure of development of the pectinate ligament. Recognising the absorbent properties of the iris the value of mitotics was at once apparent, for in the contracted state the crypts of the iris were widely distended and its surface proportionately increased. The value of iridectomy arose from the peculiar nature of an iris wound after section, as he had recently pointed out no true cicatrix was ever formed, when examined years after operation the stump was as fresh as if it had been cut post mortem. Hence it followed that iridectomy opened up a permanent channel for drainage which was not influenced by the state of the pupil, and which could always be effectively produced so long as the iris tissue had not atrophied.

Mr. PARSONS said there was no doubt that the pectinate ligament was thickened and compressed in glaucoma, but it was doubtful if this was not a secondary rather than a primary phenomenon. He thought perhaps too much stress was laid upon the absorptive function of the iris by Mr. Henderson.

Mr. A. F. MACCALLAN (chief inspector of ophthalmic hospitals in Egypt) gave an account of

Four Years' Work with the Ophthalmic Hospitals in Egypt.

The work was started in 1903 by the gift of £41,000 by Sir Ernest Cassel. A scheme was recommended by the Director-General of the Department of Public Health on the lines of the "Ophthalmic Flying Columns" then existing in Russia. Mr. MacCallan took up duty in July of that year and had to organise a travelling hospital and train native doctors in ophthalmic surgery. He and his assistant made a working tour of many of the large towns of the Delta and so gained a knowledge of the conditions under which work would have to be done. The first encampment of the ophthalmic hospital consisted of ten or 12 large Indian tents at Menuf. Work began at 8 30 A M. by visits to in-patients and operations; then came the examination of out-patients, an arduous task, as often 200 new cases came and of these 90 per cent. had trachoma and about one-third required operation. One day in each week no new cases were seen; the day was devoted to refractions, which were an increasing number. Each patient had a case-card prepared with full notes and was given a leaden disc stamped with the number of that card. A camp lasted about six months and then was removed elsewhere, not because there were no more patients to be seen in the one place but that the benefits of the hospital might be distributed. There were now two travelling hospitals at work, one in Upper Egypt and the other in Lower Egypt. There was ample work for a permanent hospital in each large town and for this provision was being made; one or more hospitals would be established each year so far as money permitted. It had been felt best to establish special hospitals and not add ophthalmic departments to general hospitals. In many general hospitals there was no room for the addition and the prospective eye patients were so numerous that they would have swamped the general patients and upset all arrangements. In one city where the travelling hospital stayed the people were so appreciative of its utility that they subscribed £5000 for the building of a permanent hospital. His staff now consisted of two English surgeons, four Egyptian surgeons, and a large staff of clerical and hospital attendants. The English surgeons' duties were to teach and to operate, they had no clerical work. The Egyptian surgeons were taken after graduation and trained for this work: their interest in the work, energy, and progress promised well; their number would be increased as hospitals were established. In all, 40,103 patients were examined at the hospitals and of these 7327 were treated either as in-patients or out-patients. 5846 operations (including the scraping trachomatous lids) were performed on 2649 patients. Cases of entropion were numerous, forming 8 per cent. There was much glaucoma, but cases were usually seen too late; in 1·7 per cent. there was absolute glaucoma. 4·9 per cent. of all people seen were blind in one or both eyes. In 1906 as many as 657 cases of cataract were seen and 225 were operated upon; a large number had severe trachoma and treatment for this was a first necessity; others had severely damaged corneæ. Mr. MacCallan gave some account of the operations which he found of greatest service, particularly in dealing with the numerous cases of entropion, and of their manner of treating trachoma. Generally, besides the direct relief of eye troubles the hospitals served a great purpose, that of teaching the fellahin the much neglected virtue of cleanliness, a point they secured by excluding all patients with dirty faces. Trachoma was rife; there were at least 6,000,000 of people infected at the present time. 51 per cent. of the pupils in the Government schools showed evidence of the disease. In 1904 he examined the boys in the school at Damietta; 56·9 per cent. showed evidence of trachoma; 9 7 per cent. had other eye affections; and 25·5 per cent. had gross corneal lesions seriously interfering with vision. It had been arranged that where permanent hospitals were established the medical officers should undertake daily inspection and treatment at the Government school; this arrangement would come into working at Tanta in October next. He hoped to be able to extend this plan to all Government schools.

Dr. CROPPER congratulated Mr. MacCallan on his work; he thought that no work done by the English in Egypt was more calculated to reconcile the people to our rule than such beneficence as this.

Dr. DE SILVA gave an account of

Lepra Ophthalmica in Ceylon.

The asylum had been in existence over 200 years and now accommodated 500 cases. Of these 101 showed signs of eye disease. There were 23 cases diagnosed as lepra tuberculosa, 33 cases of lepra anæsthetica, and 45 of mixed forms. In lepra tuberculosa episcleral growths were the commonest eye affection. The initial stage was hyperæmia, then an infiltration, and a nodule resembling a pinguecula. The growth very slowly extended to the cornea, first affecting the superficial layers, then the deeper; the iris became displaced towards the lesion. No fundus troubles were found. Vision remained surprisingly good. The average duration of lepra tuberculosa was nine years and the average age of the patients was 31 years. In lepra anæsthetica the disease progressed in a much slower fashion; the average duration was 14 years, also the average age was higher, being 42 years. Paresis of the facial nerve produced lagophthalmia, and this, if neglected, was followed by total loss of the eye. When lagophthalmia was prevented the vision remained normal, save in cases where anæsthesia of the conjunctiva and lids was observed. The mixed cases seemed most often to have begun with the anæsthetic form, and from neglect to have subsequently developed nodules. He was able to divide the group into 30 showing nodules, 15 of anæsthetic type. He concluded that lepra ophthalmica in Ceylon was most commonly observed in the nodular form. Vision remained effective for a remarkable period with severe lesions. The fundus was rarely involved. Fields of vision and colour perception were not affected. Tension was only altered secondarily. In cases where vision failed it appeared that early and judicious surgical interference would have preserved useful vision for a longer period. Lepra anæsthetica only affected the eye secondarily by fostering traumatic keratitis.

PSYCHOLOGICAL MEDICINE.

FRIDAY, AUGUST 2ND.

Dr. J. F. WOODS (London) opened the discussion on

Hypnotism

in a paper in which he stated th rience of will certainly do much good. We are glad to see that stress is laid in the preface on the danger incurred by women attempting to treat themselves in any way beyond the moderate limits here laid down, and we cannot but re-echo this warning. With this reservation this book rightly used should be of the utmost service.

JOURNALS AND MAGAZINES.

The Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., F.R.S., D. J. CUNNINGHAM, F.R.S., G. S. HUNTINGTON, M.D., A. MACALISTER, F.R.S., and J. G. MCKENDRICK, F.R.S. Vol. XLI. Third Series, Vol. II., Part 4. With plates and illustrations in the text. London: Charles Griffin.—A notice is issued with this number to the effect that after the current year the journal will appear in two independent parts. One will be devoted to the consideration of anatomical, histological, morphological, and embryological subjects and will be designated the Anatomical Part at a cost of 21*s.* per annum. This part will be edited by Professor D. J. Cunningham, associated with Sir William Turner, K.C.B., Professor A. Macalister (Cambridge), and Professor G. S. Huntington (New York). The other will be named the Physiological Part and will be edited by Professor E. A. Schäfer (Edinburgh), associated with Professor F. Gotch (Oxford), Professor W. D. Halliburton (London), Professor C. S. Sherrington (Liverpool), and Professor E. H. Starling (London). The price per annum for the four quarterly parts will be the same—21*s.* The first Physiological Part will be published in January, 1908. The contents of the present number are as follows:—1. A New Topographical Survey of the Human Cerebral Cortex, being an account of the distribution of the anatomically distinct cortical areas and their relationship to the cerebral sulci, by G. Elliot Smith, F.R.S., professor of anatomy, Government School of Medicine, Cairo. The author believes that in human brains two or three hours after death appearances are presented which can be fixed by the intravenous injection of formalin and permit the several areas having distinct physiological functions to be mapped out. Illustrations in the text show the position of these areas, as well as the functions attributed to them. 2. A Study of the Navicular in the Human and Anthropoid Foot, by T. Manners-Smith, M.A., M.B. Cantab. In this article a careful description of the navicular is given which is illustrated by no less than 26 excellent drawings of the bone in man and animals. 3. Varying Positions of the Carpal Bones in the Different Movements at the Wrist, by Henry M. Johnston, M.B., R.U.I. (Dublin). The varying relations of the carpal bones to each other in the different movements of the wrist-joint are well given and illustrated by 18 figures in the text. 4. A Brain with Complete Absence of the Corpus Callosum, by John Cameron, M.D. Edin., F.R.S.E. (Manchester). No details of the psychological conditions of the subject could be obtained. 5. A Case of Fusion of the Semilunar and Cuneiform Bones, by Adams A. McConnell, B.A. Dub. 6. A Method for Determining the Position of the Base of the Eye Sock, by Evelyn John Evatt (Cardiff). 7. The Lateral Fixation of the Cervix Uteri, by Ella G. A. Ovenden, M.D. R.U.I. (Dublin). This part contains the index and title page and table of contents of the forty-first volume of the journal and the Proceedings of the Anatomical Society of Great Britain and Ireland for November, 1906.

Man.—In the August number of *Man* Mr. H. C. Lugg describes some singular customs observed by the natives of Natal and Zululand in connexion with puberty, burial, and pregnancy. Young men on first presenting symptoms of virility are required to bathe in running water, to have their heads shaved, and to abstain from any food into which milk enters. A young woman remains in seclusion in a portion of her mother's hut for two or three months. Bodies are prepared for burial immediately after death by doubling up the legs until the knees touch the chin and binding them firmly round with a blanket; the body is afterwards placed in the grave in a sitting position. Women on becoming pregnant are treated with various medicines for several months by licensed male or female herbalists, but no males are allowed to be present at confinements.

WE reviewed in our issue of August 3rd a work by Dr. J. Dulberg entitled "Marriage and Disease," being a translation and abridgment of a well-known German work on the same subject by Professor H. Senator and Dr. S. Kaminer. In the course of a favourable review of a useful work our reviewer alluded to the price being excessive, but Dr. Dulberg has recalled to our mind that the price was fixed not without a reason, and a reason of which we must all approve. In dealing with certain sociological topics it is sometimes wise to take care that books or treatises do not fall into the hands of the too young or the merely prurient, and the most efficient method of preventing this occurrence is to price the work highly.

New Inventions.

THE AEOSAN BATH.

AT the Second International Congress on School Hygiene recently held in the large hall of the London University an interesting demonstration was given of the mode of employing the aeosan bath for the treatment of disease. The aeosan bath provides a bath effervescing with either carbonic acid or oxygen gas. The apparatus is quite simple. It consists of a series of sparge tubes or tubes provided with a number of perforations. This coil is adapted to the shape of the bath and rests on the bottom. It is attached to a cylinder of compressed carbonic acid gas or oxygen by means of a flexible tube. On giving the valve of the cylinder a turn or two myriads of small bubbles stream through the water from hundreds of points and saturate it with gas. The Nauheim effervescent bath is thus imitated, and the use of chemical salts which often corrode the bath is dispensed with. Salt and calcium chloride can, of course, be added at the discretion of the physician. The Aeosan Company of 102, Charlotte-street, Birmingham, were responsible for the demonstration.

THE "VARIABLE" ELECTRIC LAMP.

THE "variable" electric lamp contains two filaments, one of low and the other of relatively high candle-power. There are three contacts on the lamp which by an ingenious device can be made to rotate immediately under the circuit contacts. The result is that the small filament can be switched on to the circuit independently of the large filament and *vice versâ*, or both filaments may be connected. The lamp thus gives three powers at will by merely rotating it. A lamp, for example, may have a small filament giving five candle-power situated within a large filament giving 16 candle-power. Then three lights are possible—namely, five candle-power (the small filament), 16 candle-power (the large filament), or 21 candle-power (both filaments in the circuit). The economy it is possible to effect by this arrangement is obvious, while it is not difficult to think of a number of circumstances which would make the "variable" lamp of great convenience. The life of the chief filament may be spared and a saving of current effected. In short, the "variable" electric lamp affords the analogy of turning the gas up or down. The lamp may be obtained of the "Variable" Electric Lamp Syndicate of 109, Victoria-street, London, S.W.

THE TOTNES (DEVON) BOARD OF GUARDIANS AND VACCINATION.—AT a meeting of the Totnes board of guardians, held on August 16th, the report of the vaccination committee was adopted, stating that on consideration of the new order and after consultation with the public vaccinators they were of opinion that the present vaccination fees were not excessive and that no alteration should be made.

THOMSON HENDERSON (Nottingham) read a paper on

The Pathogenesis of Glaucoma and the Rationale of its Treatment.

He believed the underlying predisposition to glaucoma existed in alteration of the pectinate ligament. Sclerosis of the fibrous tissue of the structure diminished the permeability of the channels and ultimately obstruction. The sclerosis was natural to all eyes but exaggerated in hypermetropia owing to the continued traction of the ciliary muscles. Features of importance were, the absorbent powers of the iris which was not to be looked upon merely as a light diaphragm; and the quality of the aqueous which was not a true secretion but an exudate dependent on arterial blood pressure. There was a fine balance between the production of aqueous and its absorption by the iris and escape through the pectinate ligament. Excitement increased the first; dilatation of the pupil closed the crypts of the iris and diminished the second; whilst the sclerosis of age Colyer poithe third. When aqueous production was excesproportionately to thin was difficult, the iris became swollen, the short muzzled bears more [illegible] it was then that its root long muzzled ones. Crowding in the prcent and glaucoma uncommon in the Ungulata and in 600 specimens vally deexamples were met with. Want of space in the premolar region was not so uncommon but the teeth underwent a certain amount of compensatory absorption of the cemental tissue of the crowns allowing the teeth to retain their natural position. Undue prominence of the superior teeth.—A condition similar to superior protrusion of the human subject was not uncommon in horses and was known as "parrot mouth." The etiology of this question required study, especially in relation to breed. The condition was not common in other animals; an example of "parrot mouth" in a fox was shown. Complete displacement of teeth.—Premolar displacement appeared to be a well defined irregularity in the animal kingdom. Examples of this deformity were shown in a wallaby (macropus mestelsis), a monkey (cercopithecus patas), a baboon (cynocephalus babuin), and a case of complete displacement of an incisor in cercopithecus mona and in a bear. The effect of rickets upon the position of the teeth was also touched upon. It was, Mr. Colyer said, well shown in lions and tigers. The incisors, especially the outermost ones, were generally considerably misplaced and the fourth premolar was forced outwards. A thickening of the tooth sacs described by Mr. Bland-Sutton might be the cause of this.

The PRESIDENT of the section (Mr. J. MCKNO ACKLAND) thanked Mr. Colyer for his interesting paper and asked what percentage of animals in various classes showed irregularities, as it was possible only the pathological specimens coming to light gave a distorted idea of the occurrence of irregularities.

Mr. BENNETT, Mr. A. W. BAKER (Dublin), Mr. J. H. GIBBS (Edinburgh), and Mr. TURNER discussed the paper.

Mr. COLYER, in his reply, made an appeal to the veterinary surgeons to inquire into the irregularities of the teeth of animals, as a large amount of valuable information on irregularities probably affecting the deformities of human jaws might thereby be determined.

In the absence of Mr. H. A. T. FAIRBANK (London) one of the honorary secretaries read his paper on

Sarcomata of the Jaws.

For the purposes of this paper Mr. Fairbank had collected 140 cases of sarcoma of the jaws, no case being included in the series which had not been determined microscopically to belong to the sarcomata. Of the 140 cases, 81 were females and 50 males; in the remainder the sex was not stated. Sarcomata most frequently attacked the jaws before the twentieth year of age, but also occurred at all ages, fibro-sarcomata occurring at somewhat later ages than the others, endo- theliomata and "sarcomatous compositite embroyoplastic odontonus" (Eve) occurred still later. In three cases of endothelioma the ages were 45, 52, and 62 years. Of all the varieties of sarcoma in the series the youngest case, occurring at one month, was melanotic sarcoma, the oldest case, one of myeloma, was 72 years of age. 41 per cent. were under 20 years of age. Many of the tumours had started in close rela- tion to teeth, but only in 10 out of the 140 was any mention made of previous pyorrhœa or caries. In the series of cases under discussion the varieties were as follows: myeloid, 57 cases; round-celled, 17; spindle-celled, 14; fibro, 14; mixed celled, 12; embroyoplastic odontonus, 8; endothelioma, 6; melanotic, 4; chondro, 4; myxo, 2; and alveolar, 2. In five

subscribed £5000 for the building of a permanent hospital. His staff now consisted of two English surgeons, four Egyptian surgeons, and a large staff of clerical and hospital attendants. The English surgeons' duties were to teach and to operate, they had no clerical work. The Egyptian surgeons were taken after graduation and trained for this work: their interest in the work, energy, and progress promised well; their number would be increased as hospitals were established. In all, 40,103 patients were examined at the hospitals and of these 7327 were treated either as in-patients or out-patients. 5846 operations (including the scraping trachomatous lids) were performed on 2649 patients. Cases of entropion were numerous, forming 8 per cent. There was much glaucoma, but cases were usually seen too late; in 1·7 per cent. there was absolute glaucoma. 4·9 per cent. of all people seen were blind in one or both eyes. In 1906 as many as 657 cases of cataract were seen and 225 were operated upon; a large number had severe trachoma and treatment for this was a first necessity; others had severely damaged corneæ. Mr. MacCallan gave some account of the operations which he found of greatest service, particularly in dealing with the numerous cases of entropion, and of their manner of treating trachoma. Generally, besides the direct relief of eye troubles the hospitals served a great [illegible] that of teaching the fellahin the much neglected excision of the whole or [illegible] they secured by excluding it was growing. It was not advisable to make an exploratory incision. With the exception of myeloid growths the results of operation for the complete removal of those tumours was far from good.

In the absence of the reader of the paper no discussion took place.

Mr. BENNETT proposed a cordial vote of thanks to the President of the section, which was seconded by Mr. COLYER, and the proceedings then terminated.

TROPICAL DISEASES.

THURSDAY, AUGUST 1ST.

Sir RICHARD HAVELOCK CHARLES, K.C.V.O., M.D.R.U.I., I.M.S. (retired), opened the discussion on

Diabetes in the Tropics

by a paper in which he stated that, although diabetes in the tropics differed in no essential degree from that met with in Western Europe, there were many points of interest in con- nexion with locality, diet, race, and customs which rendered a discussion of the subject useful and instructive. During recent years there had been a marked increase of the prevalence of diabetes among the Hindu race. Dyspepsia was an early and constant feature of diabetes in India; so much was this the case that it might be summed up by saying there was no diabetes without indigestion—its forerunner. In Bengal it was the indolent and rich and the overworked medical and legal practitioners amongst whom the disease was found. All of these, although from different reasons, were liable to suffer from digestive disturbances. The *remote* causes of diabetes in Bengal might be attributed to the depressing climate, defective hygienic conditions, the strenuous life of cities, the severe struggle for life in altered circumstances, rich living, and too great excess of carbohydrates in the food. Amongst the more *immediate* causes excess of venery held an important place, and mental or nervous strain, fright or bereavements, in fact, *any state* in which the nervous system was overtaxed, be it in the pursuit of knowledge, business, or pleasure, might prove the direct incentive to the onset of the disease. A toxic agent or other determining cause might supervene on the condition of body set up by these taxes on strength and provoke the disease. There was evidence to show that no fewer than 10 per cent. of *Bengalis* of the better classes suffered from diabetes. Sir Havelock Charles dealt with the life insurance of diabetics and said that sugar in the urine should always be considered a great, if not an insurmountable, detriment to the acceptance of a life for insurance. Carbuncle, gangrene, and *cellulitis* were the commonest complications of diabetes in India, and he recommended early excision of the carbuncle, or, *if* that was impossible, serum injection and palliative local treatment; strong antiseptic measures were *to be* condemned. In regard to gangrene it was unwise to wait *for* the line of demarcation, especially if arterio-sclerosis was marked; the amputation should be performed above the origin of all the muscles inserted into the gangrenous part.

merely as a secondary form liable to be superposed upon any ordinary anæmia if the factors producing the primary disease were sufficiently active and powerful. Next, by the aid of the schematic table here inserted (Scheme II.), Dr. Hunter rapidly summarised his own observations and conclusions (1885–1903) and showed that the disease was a specific entity, that the primary etiological factor was a specific hæmolytic infection giving rise to a specific infective glossitis which precedes and underlies sepsis of the entire alimentary tract; that the pathological edifice raised upon these foundations was special, constant, and pathognomonic, and comprised lesions in the gastro-intestinal area, hæmolysis occurring in the portal circulation and evidenced by pigment changes in the liver and kidney and hæmolytic changes in the urine, changes in the bone marrow denoting increased hæmogenesis; that the symptoms were characteristic and could be arranged in hæmolytic and gastro-intestinal groups which were inseparable from the pathological conception of the disease and were surmounted by groups of symptoms referable to toxæmia and anæmia respectively. Dr. Hunter then referred to the confusion of the issue which had resulted from the writings of Ehrlich which put forward the theory that the essential changes were blood changes—megaloblastic degeneration—and that the disease presented no clinical features other than those

This scheme shows the observation and interpretation of Addison's anæmia (Hunter, 1885–1903). Period 1. "Its Unity, Hæmolytic Nature, Gastro-Intestinal Site, Toxic Cause, and Toxic Clinical Features" (1885–1890). Period 2. "Its Infective Origin and Lesions" (1890–1903).

extraction might be successfully performed. It was very difficult to diet people suffering from diabetes for whom the staple food was rice, and it would be worth closer investigation to ascertain whether any of the cereals recommended by the earlier Indian medical writers, such as charaka, would prove a useful substitute for rice as a diabetic diet.

Major A. H. NOTT, I.M.S., from experience gained in Bengal stated that the influence of dyspepsia in the causation of diabetes was a very doubtful point. Carbuncle, gangrene, and coma were common features of the disease in Bengal. Owing to the frequency of diabetes in Bengal the question of life insurance came frequently before medical men in practice there. Major Nott considered that with established diabetes, however well the man might appear otherwise, it was the duty of the medical man to refuse the candidate for life insurance.

Sir PATRICK MANSON said that in China diabetes was rare, although the Chinese were rice-eaters and were frequently overfed and overworked, and therefore subject to most of the conditions which had been stated to be provocative of the disease. The endemicity of diabetes in Bengal was interesting. It might be, however, that diabetes, which had been for so long attributed to food, exposure, nervous influences, heredity, and so forth, might, like other ailments with similar history, come to be proved to be due to a specific organism. Leprosy, tuberculosis, sleeping sickness, and several other diseases which occurred to one, had each in turn been ascribed to general causes, whereas they now knew that a specific organism was found to be the etiological agent in each. The diabetes of Bengal would seem also to be probably one of the germ diseases.

Dr. LOUIS W. SAMBON (London) stated that diabetes was common in Southern Europe. Glycosuria was a disease not only of man but of animals. The resemblance of diabetes to other ailments, in its clinical history and its geographical distribution, which had been shown to be due to infection by an organism, indicated a similar etiology for diabetes.

Professor HANS ZIEMANN (Cameroons) stated that the negroes of Lower Guinea very rarely suffered from diabetes, although their food consisted mainly of vegetables and bananas. Rice was seldom eaten in Lower Guinea. Exposure of the head to the sun did not seem to influence the onset of the disease in West Africa.

Major G. T. BIRDWOOD, I.M.S., mentioned that the fact of husband and wife developing the disease was a possible point in support of the germ theory of the causation of diabetes. Diabetics ought not to be accepted for life assurance policies. Carbuncles in diabetes ought to be widely and deeply excised and pure carbolic acid applied to the wound.

Mr. J. M. MALLICK (Calcutta) gave an account of his experiences of diabetes from a clinical aspect. He stated that urea eliminated by natives of India was much less in quantity than in Europeans in Europe, the difference approximating to half the quantity only. The cause was no doubt due to their food being poorer in nitrogenous material and to their deficient musculature as well as to the comparatively less active life. Muscular exercise taken regularly and continuously had a highly beneficial effect on diabetics, showing that diabetes was as much of a glycolytic as a glycogenic origin.

Mr. J. B. CHRISTOPHERSON (Sudan) said that glycosuria in the Egyptian Sudan was very rare. During a five years' experience he had only seen the disease once in an Arab. He could not believe that exposure to the sun could influence the disease as the Sudanese negroes went almost with shaved and unprotected heads.

Dr. P. J. CAMMIDGE (London) referred to the relation of the pancreas to diabetes; it seemed highly probable that the islands of Langerhans were in some way intimately associated with sugar metabolism. The lesion of this part of the pancreas might arise either by extension from the duodenum or by way of the blood-vessels. Arterio-sclerosis was a frequent concomitant of diabetes, and no doubt this condition was responsible for the albuminuria which occurred in the later stages of some diabetics.

Dr. W. CARNEGIE BROWN (London) said from experience gained in the Straits Settlements diabetes was prevalent amongst the wealthier sections of the native community, especially amongst those who were engaged in occupations involving much mental activity. He had not seen diabetes amongst Chinese coolies but frequently amongst the better off Chinamen. He recommended early and complete excision of the carbuncle which was so frequent an accompaniment of diabetes. In Dr. Carnegie Brown's opinion diabetes would seem to be an endogenous disorder of metabolism. Pancreatic remedies for diabetes, although to a certain extent haphazard, had proved wonderfully successful, both pancreatic substance and trypsin being valuable.

Mr. JAMES CANTLIE (the President of the section) said that diabetes was very common amongst Chinese who had taken to European food and wines; Jews he had found to be frequent sufferers from diabetes. There seemed sufficient evidence now to prove that any race of people unaccustomed to the food of western Europe who suddenly changed their diet or added to their diet meat, sugar, and wines were liable to develop diabetes. He had found sugar present in the urine in so many cases of fractured ribs on the lower part of the right chest wall that he was induced to attribute the condition to suspension of the natural movements of the ribs and diaphragm on that side causing abeyance of the hepatic functions.

Sir HAVELOCK CHARLES, in reply to the criticisms of the various speakers, stated that he agreed with the late Colonel Crombie in the belief that diabetes was the gout of the Bengali.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 22nd, 1829

ADULTERATION OF BREAD.

WE have received several letters on this subject, but want of room renders it impossible for us to insert a tenth of them One correspondent proposes, as the best means of checking the use of alum in the manufacture of bread, that government should impose a heavy duty on that article. He hands us the following as the "formula of the London bakers:"—Flour, 375 lbs.; potatos, 15 lbs.; salt, 4 lbs.; alum, 1 lb.; according to which, every quartern loaf contains a drachm of alum; thus, at the rate of one pound of bread a day, each consumer swallows 105 grains of alum a week. "This," he adds, "is no other than poisoning by slow degrees, and though the symptoms, languor, headache, constipation, &c., may not be noticed after a certain time, it undoubtedly lays the foundation for constitutional disease in thousands."

Another correspondent considers the baker to be less blameable than the public, whose foolish taste *it is* to prefer "the bread that is *whitest*." "It is a very common thing," observes Philo-panis, "'for both mistresses and maids to exclaim, 'Lord, baker, how brown your bread is to-day!' The latter, accordingly, puts alum into his loaves, as apothecaries put colouring matter into saline draughts, and lump sugar into powders, to humour the palates of a *discerning* public. I can assure 'Panis,' (he adds) that if home-made bread would satisfy the people, the baker would most gladly produce it; it would release him from the never-ceasing anxiety that he now feels for the 'beauty' of his bread, as well as from much of the demoralising night-work occasioned by the present system of bread-making. To please his customers, it is not enough that the bread be sweet, light, well-baked, and substantial, it must be white, flaky, and silky in the crumb, qualities alone resulting from art and labour during a process of sixteen hours. Spoiled, however, as the bakers are by this white-bread craving of the public, there is much bread sold in London that has not a particle of alum in it; but then the price is high, for it is made of the best flour. Most people choose a *cheap* loaf; the cheap loaf is of course made of cheap flour, which, to produce a white and firm loaf, must have a large dose of alum mixed with it." After condemning as very irrational the unqualified terms in which the London bread is deprecated, he concludes, by observing, that "alum is sometimes of great benefit in the preparation of bread, and laws to prevent its use would be about as wise as—'Whereas divers men and women become beasts by drinking excessively of wine, porter, and spirits, and bring themselves prematurely to the grave, it is therefore enacted, that no person or persons shall ferment, or distil, or make any of the said deleterious or unwholesome articles, under a penalty of so and so.'"

blood it must be recollected that at all rate up to the age of three years the long bones were entirely filled with red (not yellow) marrow, leaving no effective margin for new blood formation. The rarity of pernicious anæmia in childhood would suggest that the specific hæmolytic toxin postulated by Hunter as an essential factor was almost inoperative in childhood. Again, another bone-marrow disease, myelogenous leukæmia, was clinically extremely rare in childhood and the hypothesis was advanced that the comparatively common condition labelled lymphatic leukæmia was possibly the intensely acute form of myelogenous leukæmia which overwhelmed the infant before the typical granulation of the myelocyte had had time to develop, and it was suggested that the specific toxin of pernicious anæmia might similarly prove so rapidly fatal in early childhood that the clinical picture of pernicious anæmia never appeared and the possibility of the association of this disease with the acute and fatal cases of infantile purpuric anæmia was referred to. Dr. Hutchison then remarked upon the necessity for investigating the essential constituent in bone marrow which produced the good results recorded by Dr. Gullan, for while yellow marrow consisted principally of fat and red marrow only of hæmoglobin and nuclein compounds containing iron, it was difficult to attribute *a priori* therapeutic value to either form. Finally, Dr. Hutchison referred to the fact that prolonged destruction, or to speak more correctly long-continued loss of blood, did not give rise to pernicious anæmia and related a case of bleeding piles in which the continuous loss of blood extending over a period of five years gave rise to a profound anæmia in which the characters of the blood changes were those of secondary anæmia only and in which after operation and consequent cessation of the systemic drain complete and rapid recovery took place.

Dr. A. E. BOYCOTT (London) directed his remarks to

Ankylostomiasis Anæmia,

for as the anæmia of ankylostomiasis had often been called pernicious, thereby implying that its symptoms, cause, and pathological anatomy were identical with those of idiopathic progressive anæmia, it would be useful to direct attention to some of the abundant points of distinction. First, with regard to the etiology and occurrence of ankylostomiasis anæmia it should be noted that although its existence had been known for more than half a century it was only within very recent times that it had been recognised as a factor to be reckoned with in the production of chronic ill health and industrial inefficiency throughout the warmer parts of the world, and the speaker instanced the reports of the Puerto Rico Commission, which showed that fully nine-tenths of the agricultural population suffered from a profound ankylostomiasis anæmia and although the prevalence of the disease was limited in Western Europe by conditions of temperature, moisture, and oxygenation, still there were places where favourable conditions prevailed and its effects might be as severe as in the tropics. Two points of great pathological interest were then mentioned; the first, that two varieties of ankylostoma which zoologically were clearly differentiated specifically and, according to some, generically also, inhabited the same host and produced identical lesions in striking contrast to the specificity of host that generally characterises animal parasites; and the second, that many ankylostoma hosts presented no symptoms of infection beyond eosinophilia—anæmia being conspicuous by its absence. With regard to the symptoms of ankylostomiasis anæmia these were readily comparable to those of the "idiopathic" disease in so far as they were dependent upon the anæmia *per se* in each, but one practical point of some importance must be noted that the reduction in hæmoglobin as measured clinically bore a different relation to the severity of the symptoms in the two cases—for instance, a patient suffering from ankylostomiasis anæmia might be regularly engaged in fairly severe manual labour even when the hæmoglobinometer recorded from 30 to 40 per cent. only of the normal, while a case of pernicious anæmia with the same percentage of hæmoglobin would be practically prostrate and confined to bed. The blood changes, too, showed marked and fundamental differences. Histologically the majority of the erythrocytes in ankylostomiasis anæmia were smaller than normal and contained a diminished quantity of hæmoglobin. In pernicious anæmia, on the other hand, the bulk of the red cells were above the average size and the cell index was above normal. Again, in the anæmia due to the parasitic infection the total amount of hæmoglobin underwent no diminution, but the total blood volume was often doubled owing to dilution with normal plasma, and consequently as the anæmia progressed the colour index of the erythrocyte fell. This was possibly because erythrocytes were turned out by the bone marrow in numerical excess but in qualitative defect and the blood was diluted to avoid the difficulties of an increased viscosity, as, indeed, obtained in polycythæmia, while in the case of pernicious anæmia there was a real deficiency of hæmoglobin, but owing to the loss of red cells also the colour index remained fairly steady or even showed a tendency to rise as the anæmia became more profound.

Professor ALEXANDER R. FERGUSON (Cairo) who followed dealt with other aspects of

Ankylostomiasis Anæmia

and stated that the opportunities of studying the blood in this disease as it occurred in Egypt were limited to its later stages and that it was quite usual to find when the patient first came under observation that his erythrocyte count was reduced to less than 2,000,000 per cubic millimetre and that the hæmoglobinometer yielded a reading of from 23 to 25 per cent. The anæmia itself was due to different factors and the effects upon the blood must be regarded as due to their mingled action. The factors germane to the discussion were (*a*) hæmorrhage, and (*b*) intestinal sepsis, and it was the influence of the latter that the speaker wished particularly to emphasise, as he considered that it sometimes conferred on ankylostomiasis anæmia special characters which closely simulated those of idiopathic progressive anæmia. The sites of attachment of the ankylostoma duodenale became sooner or later minute septic foci and in cases where these existed in large numbers the influence of septic absorption from the intestinal tract produced its effects on the blood. In every case of ankylostomiasis examined an active myeloid transformation was noted occurring in the femur. One feature of this red, vascular, and highly cellular tissue was the multiplication of nucleated red cells, a considerable number being of the megaloblastic type, which were observed in it. The presence of iron, either free or in very unstable combination, was easily demonstrable in the liver and sometimes in the liver and spleen of these cases.

Professor I. WALKER HALL (Bristol) then contributed

A Consideration of the General Metabolism in Pernicious Anæmia,

and said that investigations into the general metabolism in pernicious anæmia had yielded somewhat discordant results. The variations being too pronounced to be ascribed to individual factors suggested that the "symptom-complex" of pernicious anæmia was the expression of the action on the tissues of more than one type of irritant. As the total metabolism did not reflect any unanimity in the cases examined nor throw any suggestive light upon the causative factors, it is necessary to look to the intermediate metabolism for further indications. The processes of oxidation considered as a whole were not materially altered. The blood contained a diminished amount of oxygen, necessitating additional labour on the part of the tissue cells to obtain the required oxygen, this over-effort resulting in exhaustion predisposing to fatty changes. It was significant, too, that sugar and starches were well tolerated. In pernicious anæmia there was no abnormal disintegration of protein, and retention of nitrogen was a common finding, and the metabolism of purin bodies was approximately normal. Amongst the mineral substances, retention of chlorides occurred in some cases; in others, however, marked losses occurred. With regard to the processes of digestion and absorption, distinct subacidity, or absence of HCl, and diminished secretion of pepsin were noted, and these secretions exhibited close relationships with the anæmia, being increased or diminished as the anæmia improved or progressed. Both the bile and the fæces contained more than the normal amount of urobilin. The fæces contained excess of nitrogen, the loss ranging from 5 to 21 per cent ; but it was uncertain whether this loss was due to deficient absorption, or to excess of secretions and infiltrations of the leucocytes, &c. The absorption of fat was not good. In many cases there was increase of fæcal fat and the fatty acids varied from 52 to 72 per cent. A feature of the blood in pernicious anæmia was the general increase in the residual nitrogen. The deepening of the colour of the urine was not yet satisfactorily explained, but the presence of hæmatoporphyrin had been recorded by Taylor and hæmoglobinuria by Schmidt. The percentage of urea N to the total and considerate administration. This pronouncement is a most important one, for it strikes at the root of a policy which has been pursued too long in India and which has only been followed by disaster—viz., the relaxation of effort because the people do not heartily coöperate. It is a policy that is evidently difficult to get rid of, but it embodies a most mischievous and useless principle. In no country in the world could a people work out by themselves a successful campaign against plague, or against any other epidemic; the governing class must steer in such storms.

◆

The Prevention of Ophthalmia Neonatorum.

IT is several years now since HERMANN COHN stated that "ophthalmia neonatorum can and ought to be made to disappear from every civilised country," yet all practitioners of experience are still only too familiar with the condition. As will be seen from our report of the Ophthalmic Section at the recent meeting of the British Medical Association at Exeter, nearly half (42·36 per cent.) of the inmates of the Sheffield School for the Blind are there on account of this disease. In 1888 the percentage for the same school as given by the same skilled observer, Mr. SIMEON SNELL, was 39·7. It would seem therefore that the last decade has not been noteworthy for any diminution of the ravages of the disease. Yet we cannot conclude that COHN'S aphorism is incorrect. It is admitted on all hands that ophthalmia neonatorum is a preventable disease: there is indeed scarcely a record of statistics in which this point is not emphasised. It is true that there has been an enormous improvement since 1881, when CREDÉ advocated his method of prophylaxis as a routine measure at all births, but none the less this grave scourge chastises our infant population.

No better survey of what has been done in the past and of what remains to be done in the future is afforded than that contained in Mr. SYDNEY STEPHENSON'S recent work on "Ophthalmia Neonatorum,"[1] which has been awarded the Middlemore Prize of the British Medical Association for 1907. All the available statistics have been collected and collated with admirable care. Lacking as such records so often are in the accuracy and minuteness of detail which are so much to be desired, two facts stand out clearly—viz., that the disease is still prevalent and that all is not being done that should be done in order to eliminate it. Mr. STEPHENSON has devoted much attention to the etiology of the disease, the only sure foundation of rational prophylactic measures. That something like one-third of the cases are due to organisms other than the gonococcus is important, since it may be utilised to minimise some of the sentimental objections to routine treatment in patients of all classes. Amongst the many weighty points brought into prominence in this excellent monograph is the fact that the gonococcal form often occurs when gonorrhœa is latent in the mother, who may indeed have been infected by gonorrhœa which was latent in the father. The evidence tends to show that infection of the baby's eyes with the causal organism occurs most commonly immediately after birth, less frequently than was once thought during birth, and occasionally several days after birth. From a review of the literature and from personal experience Mr. STEPHENSON concludes that CREDÉ'S method of prophylaxis must still be regarded as the best. As a matter of detail it is found that 1 per cent. silver nitrate is even more efficacious than the 2 per cent. solution advocated by CREDÉ, whilst the inflammatory reaction is less marked. Nearly all the bad effects which have been attributed to the treatment are due to faulty modifications in the technique advocated by the founder.

English ophthalmologists have not been blind to the gravity of the disease and its results. In 1885 a deputation of the Ophthalmological Society of the United Kingdom endeavoured to induce the President of the Local Government Board to sanction the distribution by the registrars of births of a simple notice pointing out the dangers of the disease. The Government declined on the score of expense, which was estimated at £7334. Mr. STEPHENSON'S comment is that "we grudge the expenditure of a poor £7334 per annum, when the Commonwealth is *losing yearly* upwards of one-third of a million sterling by reason of individuals disabled by the ravages of ophthalmia in infancy." Some countries are already ahead of us in their measures of prevention. Compulsory notification of the disease is in force in Switzerland, Germany, Austria, France, and many of the States of North America. There is every reason to introduce it with us, at the same time organising the means of coping with the cases. Every maternity hospital ought to have its ophthalmic surgeon, a step as yet taken only by Queen Charlotte's Hospital, London; the Rotunda Hospital, Dublin; and the Maternity Hospital, Glasgow. Other preventive measures, easy and cheap in application, and requiring only organised effort, will readily occur to those qualified to deal with the matter. We cannot but think that the disease might thus be eradicated as completely as typhus fever has been. We hope that the British Medical Association may accept the mandate of its ophthalmic section, which passed unanimously a resolution that action towards the prevention of ophthalmia neonatorum should be undertaken by the Association; and we may be permitted to suggest that the Association should combine forces with the Ophthalmological Society, already a pioneer in this field of preventive medicine. It would not be the first time that two bodies have worked together to influence the Government, and in this case they will have behind them the solid opinion of all the medical profession that ophthalmia neonatorum could be and ought to be suppressed by proper measures of precaution.

◆

Infectious Diseases in the West Indies.

SOME four years ago[1] we drew the attention of our readers on several occasions to an epidemic which had occurred recently in Trinidad, and concerning the nature of which an unfortunate difference of opinion existed between the medical symptoms of uterine cancer and mentioned the success achieved by Winter in East Prussia in this respect. Winter began his crusade "against cancer" in 1902 and it was high time that English gynæcologists took some steps in this important matter. At the present time many cases which presented themselves were too far advanced to promise much hope from surgical interference. Dr. Lockyer stated that his experience in vaginal hysterectomy for cancer of the cervix was highly unsatisfactory and in spite of the fact that there had been no primary mortality he had given up the operation. Since July, 1905, he had adopted Wertheim's method, which he maintained was the only scientific way of dealing with cancer of the neck of the womb because it minimised the risk of implantation of cancer upon freshly-cut surfaces. It did this by means of a free dissection of the vaginal tube, and by the clamping of the latter before the vagina was amputated the growth of the cervix was thus hermetically inclosed in a vaginal capsule at the time of its removal. This was the one essential point in the operation. If the vagina was accidentally incised in the neighbourhood of the growth or if it tore on removal recurrence would take place. This was the reason for recurrence in one of Dr. Lockyer's cases. Whilst free dissection of the parametrium and removal of cancerous iliac glands were important parts of Wertheim's technique, they took a subordinate place when compared with the essential encapsulation of the cancerous area by the dissected vagina. Dr. Lockyer's experience in regard to abdominal panhysterectomy for cancer of the cervix comprised 12 cases. These 12 cases represented 70·59 per cent. of all cases seen between July, 1905, and July, 1907. Whilst employing the vaginal route he had operated upon 18 per cent. of the cases seen. Two patients had died from recurrence. In one of these cases the vaginal sheath had been accidentally incised, the other was a case which had been discharged as hopeless after six weeks' stay in one of the largest general hospitals in London. Six of the 12 cases were free from recurrence. From Wertheim's statistics it was seen that in his first 30 cases the primary mortality was 12, in his second 30 cases five, and in his third series three, and from this may be gathered the encouraging fact that extended experience reduced the primary mortality.

---

[1] Ophthalmia Neonatorum. By Sydney Stephenson, M.B., C.M. Edin [illegible] o Queen Charlotte's Hospital, London, &c. Lon [illegible] Sons, Limited. 1907.

[1] THE LANCET, April 18t [illegible] and June 20th (p. 1750), 1903.

Mrs. STANLEY BOYD (London) supported Dr. Lockyer's advocacy of the abdominal route. The line of recurrence was of importance and she asked Dr. Lockyer if the recurrences to which he referred were in the glands or in the connective tissue. She had frequently seen cystitis and inability to void urine. Dr. Herbert Spencer had already suggested that this was due to drainage by iodoform gauze—the method she used—and she would like to know whether other experience supported that of Dr. Lockyer that it was undesirable to drain in this way.

Dr. F. EDGE (Wolverhampton) wished to ask Dr. Lockyer his view on the way of spreading of the uterine cancer. They knew that in cancer of the breast the spread was partially in the fascial interspace and connective tissues and that mere enucleation of lymph glands was useless. It was therefore a question whether removal of glands without their surrounding cellular tissue would tend to any permanent result in preventing recurrence.

Dr. HERBERT SPENCER (London) could not agree with Dr. Lockyer that vaginal operations were to be entirely abandoned. The history of the past, showing that the patients remained well for from five to 20 years after high amputation of the cervix with the galvano-cautery, proved that this method of operating could not be reasonably abandoned. He agreed, however, that in the more advanced cases Wertheim's operation was the proper one. The great point about the removal with the galvano-cautery was that local implantation of cancer cells was prevented. He did not use a gauze drain and still thought that the trouble with the bladder in Mrs. Stanley Boyd's cases was due to its use. He would like to point out that Werder, who had really been before Wertheim in the performance of the operation under discussion, had given up the operation because he thought the vaginal operation with galvano-cautery was better.

Dr. T. WILSON (Birmingham) said that his experience with Wertheim's operation was very unfortunate. Out of his first seven cases he lost five and during the last month he had performed it four times and had lost one case.

Dr. J. M. MUNRO KERR (Glasgow) did not think that it was fair to compare statistics of Wertheim's operation with vaginal hysterectomy. He agreed that it was not good treatment to use a gauze drain.

Mr. J. D. MALCOLM (London) supported the views expressed by Dr. Lockyer, assuming that when cancerous glands were present the operation was of comparatively little value. In early cases without infection of glands the excision of the uterus by Wertheim's method enabled the surgeon to remove the disease more freely than did any other method, and Dr. Lockyer had drawn attention to the very important point that the method enabled them to remove the growth without seeing it on any cut surface. The operation in early cases should have a very low mortality. He had for some years done a panhysterectomy wherever he had removed the uterus for fibroids and he was surprised to find how easy Wertheim's operation was. In fact, he thought that he felt more comfortable in avoiding the exposed ureters than in excising the cervix without seeing the ureters. The only scientific method was to get these cases early and to remove the parts as wide as possible as was done in any other part of the body.

The PRESIDENT of the section (Dr. E. H. TWEEDY of Dublin) said that he always performed the abdominal operation now and did not pick his cases; he operated on every case in which he thought he could relieve the woman, quite apart from curing her. The essence of Wertheim's operation was that the uterus could be drawn over the pubes and the ureters made to shine through the peritoneum. He often operated on cases far more advanced than this. If the uterus was fixed it could not be drawn over the pubes, yet in many of these cases he had operated with much relief to the patient. He did not think a heavy mortality was a contra-indication. Many women with cancer left behind after the operation went back to their work, their pain was relieved, and they might live some time. It was a cowardly thing not to give women the benefit of surgical skill even if a cure could not be promised, and he did not believe for an instant that recurrence in these patients prevented other patients from seeking relief. In early cases the mortality by abdominal operation was no greater than was that by the vagina and he quite thought that if it could be done early enough the mortality of Wertheim's operation would be brought to 10 per cent.

Dr. LOCKYER, replying, thought that the cystitis mentioned by Mrs. Stanley Boyd was due to the gauze drain. He was entirely against using the drain and had found that when he did use it he always got suppuration. The chief point of Wertheim's operation was that implantation of cancer cells could be prevented, and it was this more than the question of infected glands that made the operation so satisfactory. He could not agree with Dr. Spencer about vaginal hysterectomy being a good method. His own experience of losing seven out of 13 cases would prevent his doing that operation in the future.

Professor PAUL STRASSMANN (Berlin) read a paper upon

The Indication for, and the Methods of Operating on, Uterine Fibroids.

He pointed out that from the point of view of operation the tumour was not so important as the complications which were so often found accompanying it. He laid great stress on disease of the appendages, heart disease, pressure on the bladder, and pain. He considered that vaginal hysterectomy was a better operation than abdominal hysterectomy when it was possible to perform it, because there was no abdominal scar, and no chance of stitch abscess, or hernia, whilst patients preferred the vaginal operation. In woman over 50 years of age with bleeding the operator considered that a diagnostic curettement should be made in order to determine whether hysterectomy or enucleation should be performed.

Professor STRASSMANN exhibited a large number of very beautifully mounted

Specimens of Fibromyoma of the Uterus

which he had removed.

Dr. HERBERT SPENCER was sure that the members of the section were very much obliged to Professor Strassmann for bringing so many magnificent specimens to this country at such trouble and expense. He (Dr. Spencer) was fond of enucleation through the vagina in suitable cases. Many times he had enucleated submucous fibroids, left subperitoneal fibroids behind, and the patients had got quite well and remained free of further trouble. Dr. Spencer did not agree that the vaginal route was a good way to remove large tumours; it was not so safe; bleeding could not be so well controlled as he himself knew from experience, having lost a case from hæmorrhage after the vaginal operation. He was very glad to hear that Professor Strassmann was in health and those *as yet* imperfectly understood conditions in which, without actual disease, functions are impaired and weakened, present themselves day by day to the recruiting medical examiner. At the hospital we seek for disease, at the recruiting station we seek for health, being guided in each case by the laws of medicine in their broadest sense. With a perfect system of medical education it would be possible to imagine the medical student being forbidden to observe diseased conditions in hospitals until he had, in prisons, in workhouses, and in other public institutions, made himself thoroughly conversant with the usual types of bodily health and of existence, as modified by sex, age, and previous antecedents.

More than 30 years ago Dr. THEOPHILUS THOMPSON noted how remarkable it was that in this country, while descriptive anatomy and physiology were being so diligently studied, so little attention was ever directed to the development and proportion of the human body as a whole. We are quite familiar with the physical qualities of every bone of the skeleton, with the origin and insertion, usual and accidental, of every muscle, and with the normal course and the variations therefrom of every vessel and nerve to their final destination; but to the size, weight, and proportions of the whole body, and its variations under the modifying influences of age, sex, race, climate, food, occupation, and so on, we appear to attach little importance. Anatomical text-books are chary of giving such information even where it is available, and it would be possible for a student to win prizes over and over again in anatomy and remain ignorant of the larger facts of his science as illustrated by consideration of the body as a whole. Yet in all nature man probably exhibits the widest range of variation in type. The yearly reports on recruiting might form a valuable means of estimating the hygienic condition of a great section of the nation and of taking cognisance of the ratio, the origin, and the development of those various peculiarities of constitution which shorten certain individual tenures of life either by a premature old age of the body or by quasi-senile failure of particular organs. That recruits will be drawn largely from a class where good physique must not be looked for and where domestic environment has been faulty has, of course, to be remembered or our generalisations will be pessimistic out of all proportion to the true state of the case; as a matter of fact, deductions of this sort have already been drawn by some observers. But due regard having been paid to this fact a study of the statistics of recruiting must be fruitful in suggestion. In such a study it is obvious that we must avail ourselves of the work of successive decades of medical examiners. Old and new facts when collated, by the harmony which they exhibit, become mutually illustrative, and acquire a practical value previously unknown. Research into the statistics of recruiting might throw a side-light on the nature of epidemics, their power to modify pre-existing diseases, to increase the liability to contract other complaints, and by diminution of vital energy to lessen the resisting power of the animal economy in the presence of concurrent attacks of sickness.

Since the introduction of short service in the army, and the partial application of the same system to the naval service, the health of the people in general and that of the navy and army have intersected in an increased degree; and diseases contracted in and influenced by the Services will more and more be taken back at an early age to civil life. The diseases due to climate, venereal disease depending upon the enforced celibacy of the sailor and the soldier—these are brought into the civil community nowadays with prevalence that may be increasing. We are all of us, therefore, concerned in the good health of the recruit over and above our desire that our defenders should not suffer unduly and that our taxes should not purchase for us inferior material. The care in the selection of its recruits was no doubt one of the causes of the early invincibility of the Roman legions; and the camps, fortifications, and great highways constructed by them during peace in every country in their military occupation go to show that the men were never long confined to camps, but were kept by constant outdoor occupation of a civil nature in robust and vigorous health. The selection of the material for our national forces is a duty of the first importance and one demanding knowledge of a very high degree, not only of medicine and surgery in their various branches but of the allied sciences, which are so often studied only to be forgotten when they have once served purposes of examination; and to such knowledge must be added experience which alone can guarantee exactness in the observation of every individual and the determination of his physical peculiarities. The best medical talent available in the Services might well be drawn upon in the interests of recruiting.

Annotations.

"Ne quid nimis."

FOREIGN BODIES AS A CAUSE OF APPENDICITIS.

IN the etiology of inflammation of the appendix there is a little that we know and much that we have yet to learn. We know that in all forms of appendicitis the presence of micro-organisms is essential and that many different forms of bacteria may be responsible for indistinguishable clinical conditions. These microbes attack the walls of the appendix itself, they may pass through it and invade the peritoneum; or if they be sufficiently virulent they may lead to the death of a portion of the appendical wall and so lead to perforation and all its consequences. It is also certain that under perfectly healthy conditions the micro-organisms which habitually dwell in the cæcum and appendix have practically no power over the mucous membrane of the appendix; some predisposing factor must assist or some unusual micro-organism must be present. One of the most important of these predisposing factors is a blocking of the lumen of the appendix near its opening into the cæcum. This blocking may be the result of kinks, or external pressure, but commonly it follows some previous inflammatory change. Interference with the circulation in the appendix is also sometimes responsible for favouring the action of micro-organisms, for if the appendix becomes kinked its blood-vessels are narrowed and its blood-supply is materially affected. There is, however, another cause, sometimes merely predisposing, sometimes definitely exciting: foreign bodies may enter the appendix, or concretions may form within it, but from whatever origin they are derived no doubt can be felt as to the importance of these "appendical bodies" in furthering the in many cases not present, the collapse coming on very gradually and sometimes not at all. This applied to both forms—the complete and incomplete ruptures. As regards the treatment of the 14 cases, two died unoperated upon, three were treated by plugging, and nine were treated by hysterectomy. Of the three cases treated by plugging all the patients recovered and of the nine cases treated by hysterectomy three recovered. In all the cases of hysterectomy except one the rupture was complete, whereas in all the cases where plugging was had recourse to rupture was incomplete. Dr. Munro Kerr was of opinion that at present plugging offered a very good chance of recovery, except when the child had escaped into the peritoneal cavity.

The President of the section regretted that there was no time to discuss Dr. Munro Kerr's interesting paper and said that he thought that the chief point in these cases was to determine when to perform hysterectomy and when to plug.

LARYNGOLOGY, OTOLOGY, AND RHINOLOGY.

Wednesday, July 31st.

The President of the section (Dr. R. McKenzie Johnston of Edinburgh) in a brief address welcomed those who had come to take part in the work of the section and expressed his grateful thanks for the very great honour that had been conferred upon him in making him President of that section. In view of the important discussions, in addition to the large number of papers, they had before them he decided to set an example in brevity by withholding the address which originally he had intended to give. He would merely mention two topics and commend them for individual consideration. The first was what they ought to do to emphasise the importance of the study of diseases of the throat, nose, and ear, and what could they do to advance the teaching of those subjects? Whilst it would be generally admitted that in the past ten years there had been a vast improvement in the general practitioner's knowledge of their speciality compared with former times, still there was great room for further education in that direction. *The President* confessed that he was not an advocate for increasing compulsory courses, he would prefer to make the student realise the importance of that branch of medicine rather than insist upon his taking a course the value of which he did not comprehend beyond the getting of a certificate. Their duty was to advocate the importance of a satisfactory knowledge of the subject and to neglect no opportunity of teaching those who require it. The second topic mentioned by the President was the present status of the speciality in the world of medicine. He referred to the time, not very long ago, when they were looked upon with doubt, with suspicion, and with distrust. Now they occupied an assured and respected position and they were entitled to hold up their heads with the best in any branch of medical or surgical science. They owed this in part to the high standard set by their leading men, and to the good work done and being done by a large class of able workers, and also in no small degree to the influence of such meetings as the one they were attending.

Sir Felix Semon (London) and Dr. W. Jobson Horne (London) opened a discussion on

The Differential Diagnosis of Tuberculous, Syphilitic, and Malignant Disease of the Larynx.

Sir Felix Semon in his introductory paper summarised his experiences by saying that the differential diagnosis of the three diseases usually was easy, not rarely difficult, and in exceptional cases for a time almost impossible. Points to be considered were the following: (1) congestion of the vocal cords as an initial sign of tuberculosis, syphilis, and malignant disease (*a*, bilateral; and *b*, unilateral); (2) the difficulties of diagnosis between tuberculosis, syphilis, and malignant laryngeal tumours; (3) laryngeal tuberculosis in middle-aged or old people as a source of error in the differential diagnosis between tuberculosis, syphilis, and malignant disease of the larynx; (4) the difficulties of differential diagnosis between all three diseases when appearing in the form of infiltration; and (5) a combination of two of the diseases under consideration and consequent diagnostic difficulties. Sir Felix Semon, whilst agreeing that unilateral congestion of a vocal cord usually was the forerunner of graver constitutional mischief, warned against taking this rule as an infallible one. On the other hand, he quoted an interesting case in which bilateral congestion was the forerunner of malignant disease of the larynx. He gave a full description of tuberculous laryngeal tumours and discussed their differential diagnosis from carcinoma and gummata. He further stated that laryngeal tuberculosis in middle-aged or old people was more frequent than was usually assumed and warned against advanced age being too readily assumed as indicating malignant disease when an ulcerating tumour was seen in the larynx of such persons. This point was illustrated by the communication of several cases. The greatest difficulties, he stated, were encountered in the differential diagnosis between the three diseases when appearing in the form of infiltration of the larynx, inasmuch as the perichondritis, which might supervene in all the three diseases, might completely mask the signs of the original affection. In conclusion, he discussed the combination of two or more of the diseases under consideration and the diagnostic difficulties resulting from such a combination.

Dr. Jobson Horne, in introducing the subject for discussion, said that with a view of arriving at a solution of a problem such as the one before them it was as well to have some practical method or scheme to work upon. The scheme he was about to submit was one of elimination and he intended to approach the subject from the standpoint of the exclusion of tuberculosis. When the practitioner in regular attendance ventured an opinion upon an ambiguous disease of the larynx Dr. Horne found that it was generally correct, for the practitioner, being thoroughly conversant with the patient's previous health and family history, was in a position to exclude tuberculosis and syphilis as possible factors. The natural anxiety of a specialist was the fear that he overlooked malignant disease in its earlier stages. That anxiety was reflected in the fact that when an expert made an error in diagnosis it was usually on the side of regarding an innocent growth as malignant and not on that of overlooking malignant disease. Dr. Horne, speaking of his pathological experience, said that there had passed through his hands many specimens of tissue removed from the larynx in the belief that they would show malignant disease and which had occasioned surprise when they had demonstrated tuberculosis. In this experience he was not alone; he made this reference to errors in diagnosis in the practice of others with all humility to show that the elimination of tuberculosis was a point to be gained in the problem before them and the most practical way of arriving at a positive diagnosis of cancer. There were difficulties at times in adopting this course, but in the present day they were not so insurmountable. It would be assumed that the discussion was restricted to intrinsic disease of the larynx. Before proceeding to the objective aspect of the matter there were four facts which might be considered usefully: (1) pain; (2) vocal function; (3) fibrotic degeneration; and (4) previous local treatment. Pain was experienced relatively much earlier and more continuously in malignant disease, whereas in tuberculosis, and still more so in syphilis, there was often a noteworthy absence of pain when the larynx was at rest. Hoarseness or impairment of the vocal function—a most important premonitory sign—when persistent for a long period, was not against the disease being malignant; but a recurrence of impairment of vocal function after an immunity of a prolonged interval was consistent with a recrudescence of tuberculosis where perhaps the disease had become arrested in the lungs. Further, the character of the voice was helpful. There was this marked difference between the hoarseness occasioned by tuberculosis and that by syphilis or malignant disease. In the former the voice was weak, perhaps a mere whisper, due, as he had shown, to a myositis of the intrinsic muscles, whereas in cancer and syphilis the voice was strong though hoarse. Evidence of fibrotic degeneration in other organs pointed to syphilis, cancer, or pachydermia rather than to tuberculosis. As regards previous local treatment, it was essential to the formation of an independent opinion that the larynx should not have been spoilt by some previous application of drugs or cautery or by an attempt to remove a portion of the affected part for an examination. Passing to the objective part of the subject—namely, the laryngoscopic examination itself—Dr. Horne divided the cases into four groups, it being understood that each case was ambiguous and that they were arguing from the unknown to the known. 1. Congestion of the laryngeal mucous membrane and, perhaps, impaired motility of the vocal cord. The congestion might be patchy and limited to only one part, or it might be diffuse and involving both sides. The paresis might be bilateral. 2. Tumefaction, if not a definite tumour or excrescence, with, perhaps, congestion and ruined by badly cut feet. The worst of it is that penal laws can do little towards preventing an offence which has to be detected and brought home to the offender before he can be dealt with. Thoughtlessness, let us hope, is the root of such conduct, and possibly some good would come from the publication of warning notices.

A YEAR'S WORK IN THE GOVERNMENT LABORATORY.

THE work of the Government laboratory does not diminish, for the total number of analyses and examinations made in the two branches of the laboratory—namely, at the Customs House and at Clement's Inn Passage—during the year ended March 31st, 1907, was 173,606 against 158,939 for the preceding year. The miscellaneous character of the samples examined is not surprising when it is remembered that the examinations are made in regard to three branches of Government machinery. There is first the work connected with the revenue departments (Customs and Excise), then the work in connexion with the various Government offices, and, finally, the work relating to the administration of the Food and Drugs Act and the Fertilisers and Feeding Stuffs Act. Under the last section the officials at the Government laboratory act as a kind of court of appeal in regard to samples of foods and drugs which the public analyst has reported against. The number of samples so referred this year was 114, compared with 101 in the previous year, and amongst these there was not a single sample of a drug. Out of 111 samples examined the Government chemists differed from the public analyst in 20 cases, which is equivalent to 18 per cent. of disagreements, against 9 per cent. for the preceding official year. Most of the samples referred were milk and the charge of adulteration could not be substantiated in ten cases—namely, six as regards added water, three as to deficiency in fat, and one as to the presence of boron preservative. In one sample of milk there was present the extraordinary quantity of 95 grains of boric acid per pint. Butter was another substance in dispute, for of five samples in which the charge was the presence of an excessive amount of water the Government chemists were unable to agree with the public analyst in one case. It may be noted, however, that there was agreement with the public analyst in regard to a sample of brandy declared to contain neutral or patent-still spirit, in regard to a specimen of coffee as to the proportion of chicory present, and in regard to a specimen of spinach as to its containing a certain amount of copper. Amongst the samples referred to the Government chemists by the Home Office were an opaque white glass used in the preparation of toilet pins and found to contain 34 per cent. of metallic lead, and seven samples of oil taken from motor omnibuses at the instance of the Commissioner of Police, the oil in each case proving to be of a mineral description. The fisheries branch of the Board of Agriculture submitted curious samples in the shape of the eggs of the dogfish, with the result that Dr. Thorpe, the principal chemist of the Government laboratory, reported that the dogfish egg contains appreciably more nutriment than the ordinary hen's egg, having regard to the greater weight of shell and water in the latter, and would be a valuable article of food if its pronounced fishy taste and smell were not found to be objectionable. The inquiry had its origin in the depredations of the dogfish in the fisheries of the Devonshire and Cornwall coasts. An unsatisfactory state of things is shown in regard to the importations of milk and cream from abroad, the samples having been taken at the instance of the Local Government Board. The figures show that butter from certain countries in particular frequently contains boron preservative in excess of the amount recommended as the limit by the committee on preservatives in food. Dr. Thorpe was one of the members of this committee and yet he writes in regard to the above disclosures, "In the absence of legislation on the point and in view of the conflicting decisions in the courts I have been unable to advise that proceedings should be taken." This seems to us to be rather an over-official attitude. Similarly 67 samples of cream were examined and 56 proved to contain boron preservative, and 43 of these also contained salicylic acid. How long is this dosing of milk and cream with preservatives to go on absolutely uncontrolled? Surely the principal chemist to the Government ought to take a firmer stand than this in regard to this subject about which nobody knows more than he does. In the Excise department it is of interest to note that the analysis of certain samples of beer from publicans revealed an extensive system of fraud on the revenue by the addition to beer of solutions of sugar and water in such proportions that the dilution of the beer was not apparent except on chemical analysis. In regard to 1133 samples of beverages sold as temperance drinks 71 contained 3 per cent. but less than 4 per cent. of proof spirit, 37 contained 4 per cent. but less than 6 per cent. of proof spirit, and eight contained 6 per cent. or more of proof spirit. Herb beer and dandelion stout contained respectively 10·5 per cent. and 12·3 per cent. of proof spirit. Of the 1268 samples of beer and brewing materials examined for arsenic 49 were found to contain this poisonous metal in excess of the limits laid down by the Royal Commission on Arsenical Poisoning ($\frac{1}{100}$th of a grain per pound of arsenious oxide in the case of solids or per gallon in the case of liquids). The examination of tea proved satisfactory. The importation of essence of coffee is prohibited, "but many of the so-called coffee essences are absolutely devoid of coffee"! And so prohibition does not apply to them. From the point of view of excise this may be satisfactory but that does not justify the cheating of the public or calling a preparation by a wrong name.

THE COÖPERATION OF LOCAL SANITARY AUTHORITIES WITH THE VIEW TO THE ESTABLISHMENT OF A NATIONAL HEALTH AUTHORITY.

IN the issue of THE LANCET of May 25th, 1907, p. 1445, we recorded a resolution passed by a conference of representatives of sanitary authorities in Northumberland and Durham which met at Newcastle on May 17th, to the effect that "In the opinion of this meeting it is desirable that a permanent union of the sanitary authorities of England and Wales be established as a supreme national health authority with the object of safeguarding and promoting the public health interests of the people at large against tuberculosis and other dangers to the public health." The meeting constituted itself into a temporary committee of representatives for the furtherance of the scheme. A second meeting of this committee was held at Newcastle on July 26th, when its numbers were increased by other medical officers of health and councillors. Alderman Dr. W. H. Newton presided, and in his opening statement referred to the encouraging support which had been accorded to the movement in the medical press and other quarters. A list of subjects was approved as the basis of an invitation to county councils and sanitary authorities (urban and rural) to appoint representatives to attend a conference with the object of establishing a supreme national health authority, this authority to consider all matters bearing on the public health, including tuberculosis in man and animals, milk and meat supplies, infant mortality, occupational diseases, water-supply, vagrancy, vaccination, physical degeneration, the drink problem, the disposal of sewage, the pollution of rivers, the promotion and encouragement

Dr. P. Watson Williams (Bristol) referred to cases in which either tuberculosis or syphilis could not be excluded. In such cases a heaviness in the movement of the cord improving under vocal rest was in favour of the disease being tuberculosis.

The President of the section, in summing up the discussion, considered that it would prove to be of service to the practitioner. The appearances in these three diseases were not stereotyped; they often overlapped, so that there was no short road to a definite diagnosis. The discussion would curtail a number of mistakes and he agreed that it was important to separate the cases of tubercle as early as possible.

Sir Felix Semon and Dr. Horne thanked the section for the attention it had given their papers and replied.

Mr. W. Stuart-Low (London) read a paper on

Submucous Turbinectomy,

in which he said that the operation was intended for the reduction of an enlarged inferior turbinate body without destruction of the soft parts covering it. The operation was also applicable to the middle turbinate body. He described the details of this operation which could be carried out under a local anæsthetic. In the after-treatment he had found strips of gutta percha tissue of service in dressing the wound.

Dr. Hill, Dr. Horne, and Dr. Watson Williams, who spoke, were of opinion that the operation was one that would seldom be called for.

Mr. Stuart-Low replied.

Dr. Robert Fullerton (Glasgow) contributed the notes of

A Tumour which was Removed from the Right Tonsil and regarded as being a Teratoma.

In his absence the notes of the case were read by one of the secretaries. Drawings and microscopic slides of the tumour were exhibited.

THURSDAY, AUGUST 1st.

Dr. Watson Williams demonstrated Instruments for the Diagnosis and Operative Treatment of Sphenoidal Sinus Suppuration.

Dr. W. Milligan (Manchester) and Dr. Hill opened a discussion on

The Treatment of Chronic Suppuration of the Middle Ear without Recourse to the Complete Mastoid Operation.

Dr. Milligan, in his introductory paper, discussed the various characters of the aural discharge and also the varieties of bacteria found. Passing to the subject of treatment he divided this into four headings: First, with a view of maintaining free drainage, which was most essential, small perforations might be enlarged and the contents of the middle ear drained by means of aspiration by Siegle's or Sondermann's apparatus. Irrigation of the middle ear by means of the Eustachian catheter could only be carried out by skilled hands. Secondly, in view of the fact that a large proportion of cases of middle-ear disease were due to infection through the Eustachian tube, it was necessary to treat all pathological conditions of the nose, naso-pharynx, and mouth. Thirdly, he dwelt upon the importance of a bacterioscopic examination of the discharge as a basis for local treatment. Fourthly, he discussed the various operative measures. Local curetting through the meatus he was not in favour of, as it was difficult to determine by inspection the actual extent of the bony implication. The indications for removal or otherwise of the membrana tympani and ossicles were mentioned, but he was not an advocate for ossiculectomy.

Dr. Hill introduced the subject for discussion with a lucid review of the development of the surgery of the middle ear and of the mastoid process, illustrated by charts demonstrating the chronology of the various operations and the names of the operators. The surgical measures were considered under the following headings:—I. Incisions of the membrane and of adhesions. These alone were rarely of permanent utility but were useful for getting at granulations at the mouth of the Eustachian tube and opening up diseased spots near the annulus. II. Operations by means of curettes, snares, forceps, &c., for the removal of granulations, polypi, loose ossicles, &c., when these were well within view through the meatus. III. Ossiculectomy, with removal of most of the remains of the membrane, on theoretical grounds might appear to be the ideal operation in most cases for securing good drainage of the attic and antrum and for the better carrying out of the intra-tympanic and other local medications. In practice, however, ossiculectomy, it was contended, had only a limited field of usefulness in chronic middle-ear suppuration on account of the tendency in certain conditions to the formation of diaphragms and regeneration of membrane and of adhesions which often increased deafness and impaired drainage. Dr. Hill submitted that it was undesirable to perform ossiculectomy in the following circumstances:—(*a*) When the perforation was small. In these cases adhesions and re-formation of membrane were prone to result. (*b*) In cases with large reniform perforation, with a shortened manubrium and no adhesions nor granulations evident, and good drainage. This condition was often the result of scarlet fever, the incus was usually absent, and the hearing was often good. (*c*) Where there was a good hearing in spite of chronic suppuration. Here, should really efficient local and hygienic treatment fail, some post-aural operation—e.g., of the type of Küster or of Stacke, but stopping short of myringectomy as recommended by Stacke, Hartmann, Siebenmann, Seibe, Jansen, Malherbe, and others eight years ago, and more recently followed by Grant and Heath—was preferable to ossiculectomy through the meatus. (*d*) In cholesteatomatous conditions intrameatal operations were not as efficient as post-aural complete operations and were not free from risks and were rarely to be recommended even as tentative measures. (*e*) In necrosis of the meatal walls, especially where there was a sinus leading into the external wall of attic or into the squamous cells on the roof of the meatus, nothing short of a post-aural radical operation was likely to be of permanent benefit. On the other hand, ossiculectomy appeared to be a justifiable (though uncertain) procedure as a tentative measure which might in some few instances prove curative in the following conditions:—(1) In attic disease with perforation of the membrana flaccida with or without intra-tympanic granulations and evidence of ossicular necrosis—provided always that there were no bony fistulæ through the external attic wall or on the roof of the meatus and that there was a large perforation in the membrana tensa; (2) in evident displacements of the malleus or of the incus or of both with or without granulations—always provided there was not much membrana tensa remaining; (3) in large perforations of the membrana tensa with or without granulation, but with intermittent stopping up of discharge and recurrent headache; and (4) in large perforations where there was no marked obstruction to discharge but where granulations were seen high up in the tympanum and surrounding the ossicles. IV. Intrameatal atticotomy (usually combined with ossiculectomy) was not believed to be widely practised at the present day, though in recent years it had been resuscitated by Faulder White and strongly advocated by him. It was a question worth discussing whether this operation were often advisable even in the attic disease in view of the real, though slight, danger of wounding either the facial nerve or the internal ear—dangers which were far less likely to happen in the more open radical operation. V. Woolf's intrameatal antrotomy was apparently obsolete and unlikely to be revived.

Mr. E. Cresswell Baber (Brighton) continued the discussion and was opposed to the performance of minor operative procedure. He did not consider that in their present state of knowledge treatment could be based upon a bacteriological diagnosis.

Professor Richard Reeve (Toronto) spoke in favour of the importance of a thorough examination of the nose and structures adjacent to the ear.

The discussion was continued by Mr. Stuart-Low, Dr. Syme, Mr. George Jackson (Plymouth), Dr. H. Smurthwaite (Newcastle), Dr. Bronner, Dr. Dundas Grant, Mr. A. L. Whitehead (Leeds), Dr. A. Logan Turner (Edinburgh), and Mr. W. J. Chichele Nourse (London).

The President of the section summed up the discussion and Dr. Milligan and Dr. Hill replied.

Dr. Syme read a paper on

A Case of Acute Suppuration of the Middle Ear complicated by Septic Meningitis and Brain Abscess.

After giving a full description of this case Dr. Syme discussed the question of what had been called meningism and remarked on the difficulty which frequently arose in deciding as to whether the symptoms which made up this phenomenon were due to actual intracranial disease, to serous meningitis, or to cerebral irritation from toxins or from the proximity of acute inflammatory conditions in the bone.

of excusing pupils from gymnastics or from any classes considered injurious to their health. At the same school at Sofia, out of a class of 950, 100 were excused from certain classes during this last term. All children predisposed to, or suffering from, tuberculosis are rigorously excluded, those where the disease could be definitely diagnosed being sent to sanatoriums, and those in whom there is predisposition sent for rest and an open-air life to the Colonies Scolaires. In another communication to the Congress Dr. Pascheff said that in Sofia a benevolent society has obtained a house ten kilos from Sofia, and that it was being furnished to serve as a prophylactic home for children who were failing in health. Mrs. Watt Smyth gave further details. The medical officer to the school, she said, was responsible for the hygienic condition of the school and equipment; for the health of the scholars, especially with regard to checking infectious diseases; for the anthropometrical records; he gave lectures to the teachers on personal and school hygiene, first aid, and popular medicine; and to the scholars instruction in the rudiments of anthropometry, physiology, and general and school hygiene. This was particularly important in view of their intelligent coöperation in the future medical examination of elementary school children and the checking of infectious diseases. He made an annual report on the work accomplished; he was also consulted with regard to lessons and the framing of the time-table and with regard to punishment. He also advised as to revaccination. Very poor children, except in cases of infectious disease, were treated at school or at home by the school medical officer and food and medicine were supplied to them from the funds of the school bank. He entered in a register, signed once a month by the school director, all general notes with regard to the health of scholars, defects in the school building and infectious outbreaks. At intervals the medical officers to the schools held meetings and other practitioners were invited to take part in the discussions at these meetings. We agree with Mrs. Watt Smyth's evident view that a very complete scheme has thus been inaugurated in Bulgaria inasmuch as it insures a supply of healthy teachers, who, being trained in hygiene, will be fitted to apply its principles in the hygiene of the schools to which in due course they may be appointed.

THE ELIMINATION OF AGGLUTININS IN THE URINE OF PATIENTS SUFFERING FROM TYPHOID FEVER.

Dr. Heinrich von Hoesslin of Munich has published in the *Munchener Medizinische Wochenschrift* of April 30th some interesting clinical and experimental observations to determine whether the agglutinating substances in the blood are demonstrable in the urine. At the outset it was important to differentiate between patients in whom the kidneys were normal and those with albuminuria. He found that in the former group—i.e., patients passing urine free from protein—no agglutination was obtained with the urine, whether the agglutinating power of the blood were high or low. On the other hand, in three cases of typhoid fever with acute hæmorrhagic nephritis the urine was found to have distinct agglutinating properties, the intensity of which depended upon the agglutinating power of the blood and the amount of protein in the urine. Similar results were obtained in cases without actual nephritis but with febrile albuminuria. Here the agglutinating powers were less marked than in the cases with nephritis but were quite easy to demonstrate. These observations were experimentally confirmed in rabbits. Dr. von Hoesslin concludes that the normal kidneys are impermeable to the agglutinins, that these substances can, however, be eliminated in company with proteins in the urine when the kidneys are damaged, and that the amount of agglutinins so secreted is more or less proportional to that of the protein. It has already been shown by Pick that the agglutinins are of protein-like characters and that they can be precipitated together with the eu-globulin fraction of the blood proteins. Many views have been put forward as to the origin of the agglutinins; the spleen, the lymphatic glands, and the bone marrow have all had this function attributed to them, while Gruber is of opinion that the leucocytes are also concerned in their production, but as to the channels by which they are eliminated little or nothing has been hitherto known except that they are not found in the ordinary secretions and excretions, with the exception of the milk during lactation, in which according to Stäubli[1] they may be present in greater quantity than in the serum. They have also been found in the serum of blisters, in pericardial and pleural exudates, and in the fluid of œdema. Dr. von Hoesslin also finds that an inflammatory process increases the amount of the agglutinins in any exudate—e.g., in the cerebro-spinal fluid of a case of meningitis complicating typhoid fever the amount of these substances present was found to be markedly increased.

ANTHROPOLOGY IN CENTRAL EUROPE.

ONE of the most interesting exhibits at the *Exhibition of Prehistoric Anthropology* recently held at Strasburg was the mummy of a Greek physician of the imperial period discovered at Achmin, in Upper Egypt, by Dr. R. Forrer, the Swiss palæontologist. The mummy, which was in perfect preservation, belonged to one Paulos, surnamed Jatros, the healer. Wrapped in a *toga clavata* of fine linen, adorned with bands and circular patches of purple, the body has not the familiar outlines of a mummy but appears simply as a long parallelogram. Round the neck of the physician, who was bearded, was found a chaplet of flowers and a ribbon of honour was wound about the feet. The choice of Alsace as a typical prehistoric centre is justified by the fact that this part of Europe is especially rich in remains of the Stone Age, of which the Heidenmauer, in the Vosges, with its string of so-called Druidic remains, is a unique example. The "Collection Forrer" contains an exhaustive collection of Alsatian skulls, many of which are of the brachycephalic type peculiar to the men inhabiting Europe long prior to the Teutonic invasions. This type of skull is still common among the peasantry on the left bank of the Upper Rhine and in Switzerland, and abounds in extant charnel houses. The Eggisheim skull, which is Alsatian, is of the same epoch probably as the Neanderthal and Spy skulls, or as the Galleyhill skull from Kent. The contention, therefore, that man first appeared on the earth's surface in Southern and Central Europe has much to support it. Dr. Forrer is to be congratulated on having gathered together a truly remarkable palæontographical collection, which ranges from skeletons found with weapons and pottery in tumuli, to the rude wooden locks of a prehistoric type still used in Alsace-Lorraine farmhouses. The rapidly delivered perambulatory lecture, in which Dr. Forrer explained his collections on August 15th, was of a type which, if instituted in our museums, would do much to explain the ideas of ethnologists to English students. All classes of the public, from soldiers of the line to artizans, were among the learned lecturer's hearers.

THE GERMICIDAL VALUE OF LIQUOR CRESOLIS COMPOSITUS, U.S.P.

THE recognition of the higher germicidal power of cresylic acid (cresol) over carbolic acid has led to the introduction of numerous proprietary solutions. It is desirable that such preparations should be uniform in composition and with this

Iridocyclitis.

After a critical survey of the anatomy of the ciliary region and the processes of secretion and absorption of intra-ocular fluid, Mr. Cross, in considering the various forms of irido-cyclitis, said that sometimes they observed a fine haze in the anterior part of the vitreous just behind the lens, or dots or fine threads floating in it; this was, perhaps, the simplest sign of altered secretion from Collins's glands or of exudation from the ciliary vessels. Any mild catarrh or hyperæmia of the ciliary body was likely to be accompanied by slight superficial synchisis. Choroiditis was often associated with similar symptoms and should be suspected when synchisis was thick or dense, but extensive choroiditis might be present without vitreous opacities. Serous cyclitis was essentially a catarrhal inflammation of the ciliary body and gland; there was an increase in secretion of aqueous which might be fibrinous and contain leucocytes or even pigment cells. The more solid particles were deposited upon the back of the cornea and produced "keratitis punctata." When the secretion was albuminous it did not readily escape from the eye, so might distend the anterior chamber and cause glaucoma. Most of these cases subsided without permanent damage to the eye, but there was a tendency to recurrence. There was a form of iridocyclitis which was essentially chronic and often binocular. There was keratitis punctata and proliferation of the cells lining the anterior chamber. The exudate was fibrinous and might be deposited upon the surfaces of the iris, ciliary body, on the pars nonplica, and on the retina. Hypopion might be formed. The progress of the exudation depended on the continuance of the original irritation which had produced it. If this were removed the inflammation would cease and further exudation be checked. But the exudate once formed could only be absorbed very gradually and very slowly. In grosser cases the fibroblasts penetrated the exudate, developed fibrous tissue, and formed cicatricial bands or membranes. The lens might be bound down behind by these bands and in front by synechiæ. The ciliary body might be dragged from the sclerotic or the retina from its bed. The pupil might be occluded or the anterior chamber obliterated. Later complete degeneration of the globe might follow; the shrunken eyes, if they did not cause pain and were not the result of external injuries, might be left untouched. When the condition was the result of injury in unhealthy subjects the exudate might be purulent and pan-ophthalmitis might result. These cases of iridocyclitis found their typical expression in what was known as "sympathetic ophthalmia," although this particular form was for the most part subacute. The tension in iridocyclitis varied. In early stages it was frequently subnormal, later it might be raised to such an extent that secondary glaucoma might be produced. In the last stages the atrophic eye was soft. The name was legion of the causes producing iridocyclitis. In syphilis, both inherited and acquired, these lesions were common. In Germany tubercle was said to be the commonest excitant. Rheumatic micrococci had been shown by Dr. Paine and Dr. Poynton to cause it. It was seen in rheumatoid arthritis and in mild form in less definite rheumatoid and gouty conditions. It was not common in gonorrhœal rheumatism. It might form a complication of retinitis from diabetes or Bright's disease. It was common in septic absorptions from carious teeth, nasal, gastro-intestinal, or vaginal inflammations. Mumps, typhoid fever, cerebro-spinal meningitis, cardiac and vascular disease, anæmia had all been complicated by it. Thus it appeared essentially an "end" infection probably dependent on toxin absorption, yet it might be produced by exposure to cold, overwork, or even excessive light stimulus. The treatment of all general diatheses was of first importance, then the eye conditions improved. In all injuries thorough antisepsis must be insisted upon. Rest of the eye and of the patient was essential and the relief of pain; also reduction of pressure by leeches and purges, the use of dry heat or fomentations of belladonna or conium were of much service. Attempts had been made to increase the production of "auto-bodies" in the aqueous and blood serum by sub-conjunctival injections of 4 per cent. salt solution, of sterile air, or of sublimate or oxycyanide of mercury solutions. The use of mydriatics was essential—they relieved the engorged vessels and prevented adhesions of the pupil, and in cases of increased tension atropine reduced it. Dionine was of use in some cases. There were cases where the temporary instillation of eserine was useful for the reduction of high tension, but its continued use increased the hyperæmia. The anterior chamber might be tapped with advantage, and in obstinate cases iridectomy became necessary, particularly when many synechia formed and bombée iris threatened, but the operation must only be done when the eye was quiet.

Mr. W. T. HOLMES SPICER (London) asked what Mr. Cross intended to mean by "strumous." Did he mean tuberculous or not? He had seen one of those cases where iritis had been produced by the injection of the rheumatic coccus, but the appearance of the iris was very different to any form of rheumatic iritis they were familiar with. There were large suppurating nodules in the iris discharging pus into the anterior chamber. The condition seemed more pyæmic than rheumatic. He was not disposed to operate in acute cases. He found the coloboma generally closed again, but iridectomy in recurrent iris he found of greatest value as a preventive and curative agent. He thought eserine best avoided in all these cases.

Mr. J. HERBERT PARSONS (London) reviewed the theories of secretion from the ciliary body. Chronic and subacute irido-cyclitis were essentially toxic and the treatment necessitated the removal of the primary disorder. Intestinal disorder was perhaps the most common cause. Mr. Percy Flemming had suggested the testing of the opsonic index for bacterium coli.

Professor LANDOLT (Paris) and Mr. A. C. ROPER (Exeter) agreed that from six to 12 months of quiescence should pass before making an artificial pupil. Mr. Roper believed in the free exhibition of mercury, preferably by inunction.

Dr. J. HERN (Darlington) remarked on the unfavourable results of iridectomies in sympathetic ophthalmia.

Mr. C. DEVEREUX MARSHALL (London) agreed with Mr. Cross as to the value of atropine and if necessary paracentesis, but he thought eserine always did harm, no matter what the tension was.

Dr. REBER (Philadelphia) considered that next to treatment of the general condition iridectomy and the exhibition of dionine were of great value.

Lieutenant-Colonel H. HERBERT (I.M.S.) said that plague was a common cause of the disease in India. In most cases rapid disorganisation of the eye occurred without violent reaction. The atrophy was marked by extreme shrinkage of the cornea and perforation of the ciliary region. Mercury to the point of salivation he found of the utmost service in post-operative cyclitis.

Lieutenant-Colonel HERBERT then read a paper on

Clinical Observations on Spring Catarrh.

The paper was based on observations of 39 cases seen in Bombay during two and a half years. All but seven were males and most were under 40 years of age. All races were liable to the disease. There was no seasonal variation in Bombay; perhaps most occurred in July, the wettest month. The differentiation of obscure cases from trachoma was not always easy, but the presence of follicles in the lower fornix or of lines of scar tissue was almost diagnostic of trachoma. Discharge was rare in spring catarrh, the lids must be held everted for some minutes to produce a filmy exudate on the conjunctiva, but it was always scanty. The diagnosis of spring catarrh was clinched by examining this exudate for eosinophile cells; their profusion was characteristic of the disease; he had found it constant in this but present in no other similar condition. His observation went to show that the disease was of purely local origin, although rarely he had found some nasal trouble. He had recently tried salol in almond oil in the treatment of the condition, since this drug was inert on surface mucosæ but exerted an antiseptic action when absorbed. The results were not of much value.

Mr. CROSS, Mr. PARSONS, and Dr. J. F. CARRUTHERS (Guernsey) all remarked on the rarity of the disease in practice in England. One case in from three to four years was at most their frequency.

Mr. SYDNEY STEPHENSON (London) alluded to cases in which there was a concurrent skin affection, the so-called "summer prurigo" or solar eczema. Diagnosis of the eye condition was only difficult when it was unilateral.

Lieutenant-Colonel HERBERT, in reply, thought the disease was more common than was suspected; mild cases passed unrecognised.

Mr. R. J. COULTER (Newport, Mon.) read a paper on

The Treatment of Alternating Squint.

Worth held that alternating squint was either a stage in the developmental of a true monolateral squint, or an essential ill with malarial cramps in the abdomen and diarrhœa. On admission the abdomen was tympanitic and somewhat rigid, the temperature was 102.2° F., the pulse was 102, and the leucocytes were 9900 per c.mm. The Widal reaction was obtained. On June 5th the patient was comfortable, the temperature was nearly normal, and there was no tympanites. On June 8th, at 6.30 A.M., severe abdominal pain, most intense in the lower abdomen, appeared after the action of the bowels. The abdomen was rigid and tender in the lower part. A chill and rise of temperature to 103·6° F. followed. The abdominal rigidity increased and dulness was observed in the flanks. The number of leucocytes rose to 18,000. At noon the temperature was 105° and the pulse was 130. Vaginal examination revealed fulness and increased resistance in the left fornix. Laparotomy was performed and thick puriform fluid was found in the abdominal cavity. There was no fæcal odour and no gas in the abdomen. The appendix was normal. The ileum was examined for several feet but no perforation was found. There was a left pyosalpinx which had ruptured into the abdominal cavity. Salpingectomy was performed and the abdominal cavity was flushed with saline solution. A gauze wick and rubber tubes were placed in the pelvis. The typhoid bacillus was found in the pus. Recovery ensued. Dr. Scudder could find recorded only two cases of pyosalpinx complicating typhoid fever, but in neither was a bacteriological examination made. This case shows the importance of examining the pelvis before operating for typhoid perforation in females.

THE AWARD OF A GOLD MEDAL OF THE SOCIETY OF ST. JOHN OF JERUSALEM TO A GERMAN MEDICAL MAN.

WE have great pleasure in recording that the Prince of Wales and the Chapter-General of the Order of St. John of Jerusalem have awarded the Order's medal to Dr. Albert von Lecoq of Berlin in recognition of a splendid act of humanity and devotion. This is to be made the first occasion of striking the medal in gold, as is indeed fitting, for we doubt if ever a man before played so bravely the part of the good Samaritan. Dr. von Lecoq was travelling in Chinese Turkestan last September and met at Kashgar Captain J. D. Sherer, a British officer. They agreed to travel back to India together by the Karakoram route and had crossed the Karakoram Pass. On Oct. 2nd Captain Sherer was laid up with typhoid fever and pneumonia, and Dr. von Lecoq, after looking after him for 11 days, decided to go forward to Panacuik to bring back assistance. He did so, and nine days later arrived back with a dooly, 20 Ladakhis, and fresh ponies. We can best describe what this feat entailed by quoting from the official account:—

> To perform this feat he was obliged to travel from dawn to sunset daily for nine consecutive days, crossing the dreadful Sassar and Murghi Passes twice. During this time this gallant gentleman lived on flour balls rolled by his Anjaulik servant and then dipped in melted grease, as he left meat and other stores behind him, with a complete disregard of himself and his own health, fearing Captain Sherer would run short. On Oct. 22nd they started for Panacuik and on Nov. 2nd arrived at Leh. That Dr. von Lecoq, a mere road acquaintance of Captain Sherer's and a man of different nationality, should cross the Sassar and Murghi Passes three times in 14 days, the third time in a blinding snowstorm, the first-named pass being 17,840 feet high, and the summit consisting of some three miles of perpetual glacier, appears an act of self-sacrifice, humanity, and devotion which is deserving of exceptional recognition.

We must add that this heroic man was himself in a debilitated condition from dysentery and hard living during two years' travel on scientific research in Turkestan. It has been well said that science and humanity know no boundaries and never has it been more truly proved than by this gallant German. Captain Sherer's country has rightly marked its debt of gratitude in a signal manner to a man of whom the medical profession throughout the world may justly feel proud.

EPIDEMIC CEREBRO-SPINAL FEVER.

IN London during the month of July there were 17 cases of epidemic cerebro-spinal fever notified, of which four belonged to Islington, three to Battersea, and two to Bermondsey. In Ireland during the week ended August 17th there were six deaths from this cause registered in Belfast. In Scotland there were seven deaths registered in Glasgow, two in Edinburgh, and one in Paisley. In Glasgow the weekly report issued on August 16th showed that there were at that time 40 cases under treatment. It is announced that the governor of Dalkeith Combination Poorhouse (*Anglicè*, the master of Dalkeith union workhouse), near Edinburgh, has been removed to Dalkeith fever hospital suffering from cerebro-spinal meningitis.

THE King of Italy has graciously consented to become a patron of the International Institute for the Study of the Causes of Mental Diseases and their Prophylaxis. As a consequence, we are informed, the Italian Minister of Foreign Affairs is about to invite the various Governments to nominate official delegates to the association. It may be remembered that an international committee was formed at the Milan Congress on the Care of the Insane in 1906, and it is hoped that as many members of this committee as possible will meet at Amsterdam between Sept. 2nd and 7th during the meeting of the forthcoming International Congress of Psychiatry and Neurology. In this way it should be possible to arrange definitely the programme of work of the association.

WE regret to hear that Dr. David Nicolson, C.B., Lord Chancellor's Visitor in Lunacy, was injured while proceeding on an official visit to the Hull City Asylum on August 17th. The horse attached to a hansom cab in which Dr. Nicolson was riding having bolted, and the driver being dislodged from his seat, Dr. Nicolson jumped out of the vehicle and sustained a downward dislocation of the left shoulder-joint. This was successfully reduced and the patient is now progressing satisfactorily.

His Highness Prince Henry zu Schönaich-Carolath will be President of the Fourteenth International Congress of Hygiene and Demography. Dr. Rubner, Privy Councillor of Medicine, professor of hygiene at the Royal University of Berlin, and Professor Dr. von Mayr, Under Secretary of State, Munich, will be Vice-Presidents.

THE Royal Society has provided funds for the investigations which Dr. F. H. Scott is making with respect to the metabolic processes in nerve cells, and has awarded a studentship in biology to Dr. H. M. Woodcock in connexion with reasearches into the life-history of certain hæmatozoa of birds, to be carried on at the Lister Institute of Preventive medicine.

THE St. Thomas's Hospital old students' dinner will take place at the Victoria Hall, Hotel Cecil, on Tuesday, Oct. 1st, at 7 o'clock for 7.30. The chair will be taken by Dr. Theodore Dyke Acland.

THE King has been pleased to appoint Lieutenant-Colonel James Will, R.A.M.C. (Principal Medical Officer), to be an Official Member of the Legislative Council of the East Africa Protectorate.

PONTYPOOL HOSPITAL.—It has been decided to expend £150 upon an electrical installation at the Pontypool Hospital, which was opened in the autumn of 1903. There is accommodation for 19 patients in this institution, which was not only opened free from debt, but has also always been than sufficient for its needs. able to obtain an two forms: the one starting by a broad base from the limbus and extending as a fine stem across the cornea and giving off buds on each side; the other started as a central corneal spot from which spread branches in stellate fashion. Evidence of their herpetic nature was seen, sometimes in their earliest state, more frequently in the stellate than the proper dendritic form, when the site of the future ulcer was seen to be covered with ballooned epithelium not taking a stain, and when the epithelium was shed leaving the well-known shallow groove. At the ends of the ulcer there often appeared vesicles. The treatment of dendritic ulcers and of relapsing keratitis was discussed. In the early stages loose epithelium should be removed and atropine and bandages used to rest the eye. Cauterisation by carbolic, alcohol, or perchloride solution prevented relapses; the actual cautery was less successful. Dionine in strong solutions had been recommended and proved useful in a few cases. Mr. Spicer urged the free removal of the epithelium of the site down to the basement membrane. The general health should receive attention. Superficial punctata keratitis was discussed; it was not held to belong to this group but rather the effects of an acute catarrh of the whole conjunctiva.

Dr. J. CROPPER (Jerusalem) described a *superficial spreading* degenerative process in the corneal epithelium he had seen after trachoma had been treated by "brossage." Scraping the cornea or the application of antiseptics were of no avail, but the actual cautery had a useful effect.

Mr. RANSOM PICKARD (Exeter) said the recurrent bullous keratitis seen after scratches of the cornea so exactly reproduced the original lesions that the inclosure of micro-organisms was suggested. He thought the freer use of antiseptics was indicated in these injuries.

Mr. GRIFFITH asked if Mr. Spicer could throw any light on the process which produced the minute ulcers occurring in catarrhal conjunctivitis as a ring of dots near the margin of the cornea.

Mr. W. H. DE SILVA (Colombo) said he had seen atypical forms of keratitis dendritica which were of malarial origin, and which, unless the *underlying* condition was treated, were of a most intractable nature.

Mr. ROPER read a paper on

Extraction of Cataract without Iridectomy.

He stated that it was the traditional practice at the West of England Eye Infirmary to do the simple operation (without iridectomy) and to this he in the main adhered. The late Mr. Bankart was the unswerving champion of this operation and was not shaken in his opinion by the general practice of the operation with iridectomy by distinguished operators. In explaining the papers of statistics handed round Mr. Roper said that Mr. Bankart seldom corrected the astigmatism of the peasant class treated at the Eye Infirmary, deeming it better to give them spherical correction only. He had therefore not given the minute visual statistics of his work. The records showed, however, that of 150 consecutive cases 133, or 88·65 per cent., were simple extractions, and 17, or 11·33 per cent., were done with iridectomy. Of the 133 cases of simple extraction he had only six cases of prolapse of the iris, or 4·51 per cent. Of the cases in which V. was recorded 4 per cent. had V. = 0; 1·6 per cent. had V. less than $\frac{6}{60}$; the remaining 94·4 per cent. had V. from $\frac{6}{60}$ to $\frac{6}{6}$. Mr. Bankart thought so little of prolapse that probably no notice was taken of cases in which very slight prolapse caused the adhesion of the iris to the wound, but in his (Mr. Roper's statistics) all such cases were included. Mr. Roper's cases, 152 in number, showed 11 *per cent.* of prolapses, including those of minutest degree. Of the ten cases which resulted in V. = 0 four suppurated, two immediately, from infection at the operation, one at the tenth day, and one at the twelfth day; both the last had blepharitis before operation. One case followed hæmorrhage from the retina at the operation and another after hæmorrhage into the vitreous during a subsequent attack of bronchitis. In the one eye lost by reason of prolapsed iris there was an escape of fluid and muddy vitreous when excising the prolapse; it was probable that vision would not have been improved by operation in any case. The remainder were cases of "forlorn hope." The percentage of cases where no record of visual acuity was made seemed large but they were nearly all cases of either illiterate people or patients who were discharged convalescent and told to return for needling or spectacles but who failed to do so. From the notes of their cases it would appear that there were no surgical failures among them.

Mr. Roper advocated leaving a
upper part of the incision a
iris and prevented prolapse
sidered it neither necessary
His general plan was to exc
converting the operation in
He was guided by the amount o
state of the lower margin of the
excised a prolapse of the third, fourth,
to deal later with the cicatrix; he did no
a prolapse occurring later than the sixth day,
away the cystoid scar when it had become
organised. He had seen no cases of irido-cyclitis or s
tion following prolapse of the iris.

Mr. C. DEVEREUX MARSHALL (London) said that the simple operation of extraction without iridectomy was now frequently performed at Moorfields. One or two surgeons scarcely ever did the combined operation and he often extracted through the intact pupil. He would never leave an iris that did not return to its proper position perfectly, as such usually prolapsed within a few hours or days. If the iris bulged he did an iridectomy before completing the operation, yet in spite of every care prolapse did occasionally occur. The advantage to the patient of the simple operation was the comparative freedom from the risk of the capsule being drawn up into the wound, for when an intact iris was replaced all capsular tags were set free from the wound.

Mr. HILL GRIFFITH commented on the visual acuity obtained in some of the cases. He said that he and his colleagues preferred the combined operation.

Mr. COULTER considered prolapse less likely to occur with peripheral corneal incisions than when the incision was well within the cornea.

Mr. E. BREWERTON (London) thought that Mr. Roper was hardly fair to himself in including as "prolapsed iris" cases where the iris was merely agglutinated to the back of the wound. The danger of a prolapse was in the frequent presence of capsular adhesions also. For this reason he thought that these mishaps were so frequent a source of sympathetic ophthalmia. He would like to ask Mr. Roper which operation he would choose if he had to operate for cataract on a patient who had only one eye.

Mr. J. ELLIOT SQUARE (Plymouth) thought the simple operation worth doing for cosmetic effect in some cases—e.g., a society lady with light-blue eyes would not unnaturally object to the odd effect of a large coloboma of the iris.

Mr. ROPER, replying to the discussion on his paper, emphasised the statement that during 25 years' work at the eye infirmary he had seen or heard of no case of sympathetic ophthalmia following the simple extraction with or without prolapse of the iris. As he had always had the run of the infirmary he must have heard of or seen any such case had it occurred. He had not burdened his paper with a statement of the rather obvious advantages of the simple operation. He would do an iridectomy before extraction for a person with a chronic cough or for a woman who was likely to be restless after operation, or if synechiæ were present. A post-operative iridectomy was indicated where the iris showed a strong tendency to prolapse or where it had been much bruised or its pigment stripped off in the course of the extraction. The chief criticisms of his methods had been advanced against his corneal incision as opposed to the evidently more general peripheral one and of his opinion that a prolapse need not always be excised. He could only say with regard to the latter that his experience had shown him that it was often sufficient to dissect off the cystoid cicatrix and that the eyes did perfectly well without the more dangerous procedure of opening up the wound and searching for the iris which could not always be seized. Astigmatism after operation was from 1 D. to 2 D., usually about 1·5 D., and almost invariably had an axis of 150° or 30° below the horizontal. Mr. Brewerton had asked him what he would do in the case of a person with but one eye. He had such a case four or five years ago and, with the courage of his convictions, did his usual operation. On the fourth night the patient had bad nightmare and her struggles with an imaginary foe caused a large prolapse which he excised at once. She left the infirmary with vision $\frac{6}{9}$ and was so recorded in the results before the meeting. About three weeks since she came up for new spectacles and her vision = $\frac{6}{5}$ every letter. He was certain that strain of some kind was the chief cause of prolapse.

Notwithstanding the great mortality he thought that the combined method had a certain field of its own, especially when it could be foreseen that the removal by the sacral method would be too difficult or incomplete, or where such proved to be the case after a beginning had been made with the sacral operation.

Dr. JOHAN NICOLAYSEN (Christiania) reported two cases of Chronic Ileus, and Dr P. BULL (Christiania) one of Volvulus of the whole of the Jejunum and Ileum.

Professor ALI KROGIUS (Helsingfors) illustrated and explained an ingenious method of treating the duodenal stump remaining after resection of the pylorus, so as to avoid the various unpleasant sequelæ which often arise from its defective treatment.

Professor BORELIUS read a paper on a series of 43 cases of Stone in the Ductus Choledochus. From July 1st, 1898, to July 1st, 1907, he had operated on 180 cases of gall-stone and had performed choledochotomy in 30 cases with six deaths. Of eight cases of stone in the ductus choledochus not operated on four died, while of six patients who were only incompletely operated on all died.

Professor TH. ROVSING (Copenhagen) said that in several cases in which a choledochotomy proved too difficult he had done a sort of choledocho-lithotripsy, gently crushing by means of two fingers the stones in the bile duct, so that the fragments might be pushed down into the intestine. Where this procedure did not prove efficient he had sometimes succeeded in forcing the stones from the bile duct back into the gall-bladder by grasping the duct firmly below the stone between two fingers and exercising a pressure in the direction upwards. In such cases it was, of course, necessary to prevent the stone from impacting itself in the hepatic duct.

Professor ROVSING communicated a note on the Antiseptic Properties of Nitrate of Silver. For many years he had been constantly using it and now preferred it to all other antiseptics in the overwhelming majority of circumstances where antiseptics were needed. His reasons for doing so were that, though not poisonous to the human body, it was one of the strongest antiseptics known, and that it retained its bactericidal power also when converted into albuminate or chloride of silver. He recommended it particularly for the impregnation of gauze for dressings. It had enabled him to do away entirely with iodoform gauze in his hospital—e.g., he always used "lapis-gauze" for replenishing the Mikulicz bag in laparotomies. "Lapis-catgut," the preparation of which was exceedingly simple, was absolutely safe and trustworthy as to sterility, agreeable to handle and tie, and, as tests had proved, stronger than raw catgut, while all other methods of preparing catgut lessened its strength. Moreover, "lapis-catgut" kept its strength for years, while iodine-catgut soon became brittle.

Professor TSCHERNING (Copenhagen) said that he also thought nitrate of silver an excellent antiseptic. It had been in use as such for many years at the Kommune Hospital of Copenhagen. The preparation of nitrate of silver catgut had been published years ago by a Norwegian colleague.

On August 9th an interesting discussion on the Treatment of Inflammatory Diseases of the Adnexa Uteri was opened by Professor OTTO ENGSTRÖM (Helsingfors) and Professor JOH. KAARSBERG (Copenhagen). While Professor ENGSTRÖM gave a lucid exposition of the different methods of treatment, operative and not operative, Professor KAARSBERG contributed to the Congress a conspectus of 289 cases on which he had operated. Perhaps the most important feature about his communication was the information it contained about the after-history of nearly all his operation cases. Professor KR. BRANDT (Christiania), Professor F. WESTERMARK (Stockholm), and Dr. H. FORSSNER (Stockholm) took part in the discussion.

Professor TSCHERNING demonstrated an original operation which he had devised for the removal of malignant new growths in the lower part of the hypopharynx and the adjoining part of the gullet. In contra-distinction to all other operations it spared all important nerves and vessels and gave an excellent view of the diseased region, far better than a lateral or subhyoid pharyngotomy. An incision was made in the middle line of the anterior surface of the neck, a low tracheotomy performed, whereupon the anterior wall of the larynx, with the hyoid bone and the uppermost rings of the trachea, was divided in the middle line. After inspection of the anterior of the larynx Professor Tscherning divided also the posterior wall of the larynx and the upper part of trachea in the middle line, and by inserting retractors on the pharyngeal and œsophageal surface of the severed cartilages he could with the greatest ease inspect and, if needed, excise every wrinkle and fold of the mucous membrane of the hypopharynx and uppermost part of the gullet. In the cases operated on the bleeding had been practically *nil*, this being one of the advantages of the operation. Moreover, it spared the vocal apparatus, at the same time giving just as good a view of the diseased region as if a laryngectomy had been performed.

The application of X Rays to the Service of Surgery formed the theme of three communications. Professor JOHN BERG (Stockholm) demonstrated a series of photographs of Stones in the Urinary Bladder and related how in more than one case the x rays had been of inestimable value to him. He had in one case emptied the bladder of stones and had assured himself of the thoroughness of the operation by searching it carefully with his finger. Nevertheless, the patient's symptoms continued and on the photograph there appeared a shadow of a stone. A second operation at first failed to locate the stone, but after much searching he succeeded in finding a diverticulum with so narrow an opening that he could not get a finger-tip through it; the stone lay in this diverticulum. In other cases the x rays had helped him to diagnose prostatic stones.

Dr. O. BORCHGREVINK (Christiania) illustrated by x ray pictures the results of his ambulatory extension treatment of fractures of the upper limb. His apparatus was very simple, using only rubber tubing as extending force. The results, also in the difficult cases of supracondylar fracture of the humerus, were above all praise.

Dr. P. TETENS HALD (Copenhagen) showed a series of Roentgen pictures demonstrating the great help that might be derived from them in the diagnosis of affections of the accessory sinuses of the nose. While the healthy sinuses were clear and had distinct outlines, the diseased ones appeared blurred or seemed to have entirely disappeared. That the sinuses were present even in the last-mentioned cases was proved by the photographs showing probes introduced into them. Photographs of affections of all the accessory sinuses were shown and some interesting cases related illustrating the value of the method in diagnostic difficulties.

(To be continued.)

SECOND INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

THE EXHIBITION.

IN connexion with the Second International Congress on School Hygiene an exhibition of school buildings and furnishing appliances was held in the central hall and adjoining rooms of the University of London. The exhibition was wide in scope and members of the Congress and others took the keenest interest in the various exhibits which illustrated recent progress in educational methods not only in this country but in Austria, Denmark, France, Germany, Holland, Italy, Spain, Sweden, and Switzerland.

Many of the stalls necessarily embraced exhibits which under a scientific classification would naturally fall under different categories, but for the purposes of this notice the exhibits may be conveniently divided into two sections, the first dealing with buildings, and including materials of construction and sanitary arrangements, and the second dealing with furnishing and equipment, including teaching and technical appliances.

Under the heading of

School Buildings

may be included the numerous and useful loan collections of drawings, plans, and designs. One of the chief attractions was the collection of exhibits from schools under the control of the London County Council. The details of medical supervision were admirably shown by means of charts and diagrams, while the plans and elevations of the different types of schools under the control of the Council gave the visitor to the exhibition an excellent idea of the work that is being done by this body. Several interesting exhibits were shown by provincial schools and the Scottish section illustrated the keen interest that is taken in education north of the Cheviots. One object in the English loan collection which bore no label, but which was apparently intended to illustrate to children a lesson on the care of the baby, was a cradle containing a large doll. Though roughly made the hypnotism as a therapeutic agent in cases of insanity dated from 1892, when he was acting as medical superintendent at Hoxton Asylum. He had now treated 2076 cases in all, of which number he had classified 881 as mental cases, including neurasthenia, hysteria, bad temper, &c., most of which were borderland cases, in which this form of treatment was most efficacious. His figures were as follows:—

Mental and Borderland Cases.

—	Number of cases treated.	Recovered.	Improved.	No apparent change.
Neurasthenia or borderland cases	666	597	41	28
Melancholia	118	90	19	10
Delusions	2	2	—	—
Mania	44	20	16	8
Night terrors	6	5	1	—
Stage fright	28	23	5	—
Phobias	5	4	1	—
Delirium tremens	1	1	—	—
Hysteria	7	5	1	1
Obsession...	2	2	—	—
Bad temper	2	2	—	—
Totals	881	741	84	56

He illustrated his paper with notes on three cases of melancholia and one case of puerperal mania that recovered under the influence of hypnotic treatment. He mentioned the different methods used in the operation for inducing hypnosis, having the primary object of engaging the attention and fatiguing the visual apparatus. Of late years most physicians had found that it was not always necessary to induce complete hypnosis to render suggestion effective. A great many of his patients were susceptible to suggestion if he merely sat by them and obtained their attention. It was a common practice with him to place one hand on the patient's epigastrium while gently stroking with the other the patient's head and then engaging him in conversation with the object of securing his full confidence. He then got the patient to relax his muscles to the utmost. He insisted on complete silence and the suggestion was made at the psychological moment. There must be no kind of uncertainty about the manner of making the suggestion, it must be forcible and emphatic. He probably never treated two patients exactly alike, but he felt the procedure was an instinctive one. He stated that he could not tell at once whether a patient was susceptible or not and that many responded after repeated trials. Dr. Woods then gave a detailed list of all the cases treated, non-mental as well as mental, the list including, amongst others, epilepsy (12 recoveries and 22 improved out of a total number of 50), hay fever (five cases, all recovered), writers' cramp (ten cases, six recoveries), headache (214 cases, 186 recoveries), dyspepsia (65 cases, 59 recoveries), and neuritis (41 cases, 27 recoveries).

The PRESIDENT of the section (Dr. T. CLAYE SHAW of London) who followed reminded those present that not long ago hypnotism was very largely under suspicion but that nowadays it was becoming a recognised method of treatment and that in the light of results obtained by responsible physicians like Dr. Wood, who stated that cases of epilepsy had recovered under hypnotic treatment, it appeared certain that some persons suffering from diseases which involved organic bodily changes recovered under the treatment.

Dr. E. S. PASMORE (Croydon), Dr. A. T. SCHOFIELD (London), and Dr. W. F. MENZIES (Cheddleton) having questioned the author as to the nature of the cases and the duration of the "cures,"

Dr. D. YELLOWLEES (Glasgow) expressed his doubt on both these points with regard to Dr. Wood's results. He believed, however, that hypnotism was valuable at times in relieving pain, even in cases of organic disease, and instanced in this relation some cases of locomotor ataxia in which he had found hypnotic suggestion alleviate the more painful symptoms.

Dr. G. M. ROBERTSON (Larbert) gave the results of his 20 years' experience of hypnotism, an experience which had resulted in a gradual cooling of his original enthusiasm for the treatment. The favourable results of treatment bore, of course, only on the mental side of the subjects, such mental affections being present both in functional and organic disorders, and were in his experience not lasting. He had found it very difficult to induce hypnosis in insane people and particularly in melancholics.

The discussion was closed by the PRESIDENT of the section who stated that he could not but come to the conclusion that states of mind had an enormous influence on states of the body.

Dr. SCHOFIELD contributed a paper upon

The Teaching of Psychology in Medical Schools,

in the course of which he animadverted upon the "extraordinary fact" that the subject of psychology—using the term in its broad sense of the study of mind, normal and abnormal—had in England "hardly a teacher, a student, or a text-book," and pleaded for the curtailment of the ordinary medical curriculum in certain directions—e.g., in materia medica, minute anatomy, and so on—in order to make room for the study of weightier matters concerned more nearly with life and death, health and disease, such study to include "normal psychology, surgical psychology, the psychology of etiology, psycho therapeutics, the psychology of drugs, applied mental therapeutics, the psychology of the patient (body, soul, and spirit), and the psychology of the physician himself."

Dr. SCHOFIELD'S paper did not evoke discussion, but Dr. F. W. EDRIDGE-GREEN (Hendon) and the PRESIDENT of the section both agreed that it would be well if more attention were given to general psychology as a necessary preliminary to medical psychology.

Dr. PASMORE (medical superintendent of Croydon Mental Hospital) exhibited and explained his "flag diagram" for recording the family histories of patients.

The meetings of the section then closed.

DENTAL SURGERY.

FRIDAY, AUGUST 2ND.

Mr. F. J. BENNETT (London) read a paper entitled

"*Some Anatomical Results of Efficient Mastication.*"

He said that as the signs of attrition had become less in advancing civilisation so defects of the jaws and teeth appeared to have increased. One of the most common results of efficient mastication was a well-shaped and large arch of the jaw. The cause of the attrition often observed in old skulls was apparently related to the oblique manner in which the lower teeth were erupted; this resulted in unequal wear of the inner and outer cusps of the molars, the obliquity and the wearing of the internal cusps assisting in spreading the teeth outwards, and enlarging the dental arch; not only this but the incisors tended gradually to come edge to edge. Attrition was apparently too late a development in the human subject to allow of it being fully fixed to have become inherited. In many cases, however, a modification of the shape of the teeth had occurred, the teeth had become broader and flatter and the fissures less well marked. When the teeth subjected to attrition, due solely to vigorous muscular action, were compared with the teeth of the present day showing every mark of deterioration the question of the possibility of improvement of the jaw muscles by appropriate exercises at once suggested itself. Mr. Bennett then went on to describe a curious parasitic group which he had found attacking the teeth in certain skulls which had been dug up in Ireland. The growth, a species of mycelium, had grown down throughout the denture of the teeth in question, apparently being a purely post-mortem phenomenon. Slides were shown exhibiting the appearances found.

Mr. J. F. COLYER (London), Mr. K. W. GOADBY (London), and Mr. J. G. TURNER (London) discussed the paper, and Mr. BENNETT replied briefly.

Mr. COLYER read a paper on

Irregularities of the Teeth in Animals.

He said that no work of the dental practitioner required more thought and reflection than the treatment of irregularities and it was only somewhat recently that attention had been directed to the origin and etiology of the various irregularities often empirically treated. He had recently directed his attention to the irregularities of animals' teeth with a view to throwing some light on the etiology of the human types of malposition, &c., and although little had equipped educational gymnasium as applied to Ling's Swedish system and a collection of anthropometric apparatus.

Miscellaneous.

Among the miscellaneous exhibits may be mentioned the oxygen bath of the Aeosan Company, 102, Charlotte-street, Birmingham, which is described on p. 517 of this issue. The "Sanitas" Company, Limited, Locksley-street, Limehouse, London, E., showed their various specialities, as did also Jeyes' Sanitary Compound Company, Limited, 64, Cannon-street, London, E.C.; and Messrs. Newton Chambers, Limehouse, E., exhibited their "Izal" toilet and other preparations. Messrs. N. and N. C. Bletchley, anatomical and orthopædic boot manufacturers, 89, Northgate-street, Gloucester, showed a wide selection of boots and shoes for both normal and abnormal conditions of the foot and a special bandage for weak ankles. A boot made by them with a flexible sole for ordinary use should be both useful and comfortable in cases of tender feet—most difficult cases to remedy as many surgeons know. Mr. D. H. S. Brown, 72, Hartfield-road, Wimbledon, among other things, exhibited pillow-slips and sheets the chief feature of which is a tuck running across the fabric in order to distinguish the two sides, with the object of insuring that one side only shall always be kept next the body. He also exhibited an improved support for ladies' garments. Among the publishers who exhibited books on physiology and hygiene were Messrs. Macmillan and Co., St. Martin's-street, London, W.C., and Messrs. Constable and Co., 10, Orange-street, Haymarket, London, S.W.

MEDICINE AND THE LAW.

The Verdict "Felo de se."

THERE are numerous cases of persons slaying themselves as to whom there is no evidence adduced to the inquest jury of unsoundness of mind, either recent or remote. Public sentiment, however, has rendered a formal verdict "that the deceased killed himself during a state of temporary insanity" almost invariable. Following what appears to be the present-day custom of coroners, Dr. W. Wynn Westcott has usually been observed to conclude a short summing up in these cases with the question: "Will you say that this act was done during a state of temporary insanity?" During a recent week it appears that this coroner has varied his practice and has concluded by addressing the jury in these terms, "As no evidence of insanity has been laid before you are you of opinion that the deceased did wilfully kill himself and hence is *felo de se?*" In five cases during one week in three different parishes have inquest juries without the slightest moral pressure beyond this simple suggestion brought in verdicts of *felo de se*. The cases were all men. Three were at the Hackney court, all having been found in the River Lea, one, aged 74 years, afflicted with a chronic illness and *tædium vitæ;* a second, aged 62 years, suffering from poverty and lack of work; and a third, aged 53 years, a drunkard who had quarrelled with his family; one was at the Shoreditch court, his age being 51 years, he was a drunkard on the verge of delirium tremens when he took hydrochloric acid; and the last case was at Bethnal Green, an ex-prisoner, aged 38 years, who could not find work, and who took oxalic acid. The lay press, in commenting on these facts, has referred in several places to the incident as "a return to more blunt but more truthful verdicts." Probably there is a better, because truer, explanation. The inquest juries concerned were composed wholly of men of a moderate standard of education. Among such the final suggestion in the summing-up of the facts and probabilities of the case made by the president of the court would have a great influence in their minds when immediately afterwards they considered the terms of the verdict. Suggestion must have a great influence over jurymen whose knowledge of pathological conditions and legal technicalities is very small, if it exists at all; hence much may depend upon the bias of an individual coroner as to how an inquest jury will frame its verdict.

Kaloo Nuts sold for Human Food.

A trader in the City, named Brinkley, who had dealt in nuts for 16 years, recently made an experiment of a dangerous kind and may be congratulated that no worse result ensued for himself than a fine of £5 at the Tower Bridge police-court. According to his story, in telling which he appears to have been perfectly straightforward, he was introduced by a man, whom he described as an old traveller, to a ship's captain who had some nuts to sell of a kind not usually seen in England and he bought some. He ate several himself without any untoward result, and without any further precaution put them within reach of the public by disposing of some to a costermonger at the price of 7*s.* 6*d.* per hundredweight. The costermonger advertised them on his barrow as "the king of nuts, Kaloo, from South America," and found sufficient customers to cause several children to be taken to Guy's Hospital suffering from poisoning. One of these, who had only eaten two nuts, nearly died, and two others gave evidence at the police court to the effect that they had eaten six and seven respectively before being taken ill. Investigation by the police followed, the costermonger was traced, and the merchant who supplied him was summoned. Mr. Alfred Long, chief sanitary inspector to the borough of Southwark, gave as the result of his inquiries at Kew and elsewhere that kaloo nuts come from Central China where oils used for varnishing are extracted from them, which oils have poisonous qualities. He could find no trace of any importation of them to England during the last 50 years among firms engaged in the fruit trade in the City. Mr. G. Millson, medical officer of health of the borough of Southwark, had examined the nuts and gave evidence that apart from their inherent unwholesome qualities the nuts in question were rancid and in such a condition as in any case would render them unfit for human food. In fining Mr. Brinkley, who had sold them to the costermonger, Mr. Chapman made the observation, from which none will dissent, that to put a novelty upon the market with the intention that it should be eaten involved the responsibility of first ascertaining whether it was fit for human food or not. Mr. Brinkley is reported to have said that he had been in the nut trade for 16 years and that this was the first time that he had heard that a nut was unfit for food.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Liverpool.—The population of Liverpool in 1906 was estimated at 739,180. The birth-rate was 32·6 and the death-rate 20·2 per 1000. The infantile mortality amounted to a high figure, 171 per 1000 births, but there was during the year considerable prevalence of measles. Amongst the agents upon which Liverpool relies for the reduction of this infantile mortality are hospital accommodation for infants suffering from measles and whooping-cough, together with special arrangements for the earliest possible notification of births, and a staff of female inspectors. For mothers who are unable to suckle their young a suitable food is provided which is "within the reach of all." Typhus fever was introduced into Liverpool on three separate occasions during 1906, the introducers being Russian emigrants. The total number of cases occurring was 52 and the disease still claims some 20 deaths annually. Dr. E. W. Hope speaks appreciatively of the system of the voluntary notification of pulmonary tuberculosis which has now been in vogue in Liverpool for several years. During 1906 there were 1842 cases notified, a very considerable number when regard is had to the fact that the notification is voluntary and that notifications are only asked for in cases where, in the opinion of the attending medical practitioner, a useful purpose is likely to be served by visits from the sanitary staff of the municipality. As regards the control of milk-borne tuberculosis, to which subject the recent report of the Royal Commission on Tuberculosis has directed public attention in an accentuated form, energetic steps are being taken in Liverpool under the Liverpool Corporation Act, 1900, which confers powers upon officers of the corporation to visit farms and to examine cows in districts outside Liverpool from which milk is introduced into the city. The Act also enables the officers to take samples of milk at the railway stations. During 1906 tubercle bacilli were apparently discovered in milk from Cheshire, Lancashire, Staffordshire, Shropshire, and North Wales. Dr. Hope reports that both the farms and the cows in the country districts are markedly inferior to those within the city, and he furnishes photographs showing the deplorable condition of some of the country cowsheds as regards light, ventilation, cleanliness, a It will be a source pnotism as a therapeutic agent in cases of insanity dated om 1892, when he was acting as medical superintendent at oxton Asylum. He had now treated 2076 cases in all, of ich number he had classified 881 as mental cases, cluding neurasthenia, hysteria, bad temper, &c., most of ich were borderland cases, in which this form of treatent was most efficacious. His figures were as follows:—

Mental and Borderland Cases.

—	Number of cases treated.	Recovered.	Improved.	No apparent change.
urasthenia or orderland cases	666 •	597	41	28
lancholia	118	80	19	19

the treatment. The favourable results of treatment bore, of course, only on the mental side of the subjects, such mental affections being present both in functional and organic disorders, and were in his experience not lasting. He had found it very difficult to induce hypnosis in insane people and particularly in melancholics.

The discussion was closed by the PRESIDENT of the section who stated that he could not but come to the conclusion that states of mind had an enormous influence on states of the body.

Dr. SCHOFIELD contributed a paper upon

The Teaching of Psychology in Medical Schools,

in the course of which he animadverted upon the "extraordinary fact" that the subject of psychology—using the term in its broad sense of the study of mind, normal and abnormal—had in England "hardly a teacher, a student, or a text-book," and pleaded for the curtailment of the ordinary medical curriculum in certain directions—e.g., in materia medica, minute anatomy, and so on—in order to make room for the study of weightier mas, 4·0; Eurasians, more nearly with life and death Christians, 0·62; and Parsis, study to include "The possibility of diabetes being contagious the psychology not be lost sight of. Of the 325 cases oxalate of lime loo

to reduce the specific gravity and the quantity of sugar, but its prolonged use was followed by anorexia and gastric troubles.

Dr. R DEVENDRANATH ROY, Bahadur (Calcutta) stated in his paper on

Diabetes in India

that the number of people belonging to the professions of law and medicine and in persons engaged in clerical work diabetes had undoubtedly increased to a great extent in late years. He gave an interesting account of what the ancient Hindu physicians said about the disease, and although there was nothing of pathological interest in the records of their observations it was amazing to find how accurate were their clinical accounts of the disease. They distinguished between pramcha or madha-meha (sweet discharge) and soma-roga or diabetes insipidus (water disease). The causes these ancient physicians regarded as provocative of diabetes were sexual excesses, grief, hard manual labour, mental worry, lassitude, indiscretion in diet, and dyspepsia. The complications they mentioned were inflammations of various kinds, skin eruptions, furuncular eruptions with formations of pus. The diet recommended by these old observers consisted of the following articles: new rice, curd, flesh of animals living in swamps, fish, wines, vinegar, oils, onions, barley, flour of old wheat, dâl of several kinds, sesamum seeds, meat juice, old honey, whey, sparrows, pigeons, rabbits, snipe, peacock, and venison. Restriction was placed upon drinking milk and eating fish and meat at the same meal, sugar-cane and its preparations, excess of acid and salt. Jambul, seeds and roots of lotus, dates, bitters, and astringents were the therapeutical agents employed in the treatment of diabetes. Dr. Roy stated that the specific gravity of the urine of the Bengalis was lower than that of Europeans living alongside of them. He laid stress upon the general prevalence of dyspepsia amongst diabetics.

Dr. SATYASARAH CHAKRAVARTI (Calcutta) contributed a paper entit'ed

"*Notes on Diabetes Mellitus.*"

He stated that diabetes was essentially a disease of town life and was rarely met with in villages. In Calcutta the total mortality from diabetes and its complications was declared to be about 10 per cent. of the total mortality. The liability to the disease seemed to be increasing amongst Bengalis in Calcutta of late years, and especially amongst the educated Bengalis. He believed the relative immunity enjoyed by the working classes as compared with persons higher in the social scale was due to their freedom from the nervous strain inseparable from the anxieties attendant upon persons pursuing intellectual occupations in large towns. These inevitable worries affected the digestive powers as well as the assimilation of food and so predisposed to diabetes. Hindus were more often attacked than were Mahomedans, and of the Hindus those who took a mixed diet and were given to the use of alcohol were more liable to diabetes than were vegetarians like the Jains and Marwaris. The Jews were subject to the disease to a larger extent than were Europeans. This difference of incidence, however, was detected in 26·50 per cent., and uric acid diathesis occurred in 14·70 per cent. Albuminuria, pulmonary tuberculosis, carbuncle, cellulitis, gangrene, and cataract were the more common complications observed by Dr. Bose.

Dr. F. M. SANDWITH (London), from experience gained in Egypt, stated that diabetes was one of the common diseases met with amongst Egyptians. Their diet consisted chiefly of bread and vegetables, whilst sugar was consumed freely. The necropsies of cases met with in Egypt showed neither atrophy nor fibrosis of the pancreas. Dr. Sandwith inoculated four diabetic patients suffering from tuberculous lung trouble, but in no case did reaction to injection of Koch's tuberculin occur. He considered it inadvisable to allow diabetic patients to take long journeys. He had seen three visitors who had been recommended to winter in Egypt die within a few days of their arrival in that country. Treatment should consist of first lessening the quantity of sugar in the urine by strict diet and then opium, 1 grain thrice daily. Aspirin in from 5 to 15 grains thrice daily was efficient in diabetes provided there was no gastric or kidney disturbance. The Egyptians used a pill of ox-gall and the seeds of Trigonella fœnum græcum—the "helba" of Egypt. Dr. Sandwith tried this treatment but did not find it beneficial.

Lieutenant-Colonel G. M. J. GILES, I.M.S. (retired), whose experience of diabetes was gathered chiefly in the North-west Provinces of India, stated that the disease was not more common in that locality than in Europe and that the frequency of cases of diabetes amongst Bengalis in the North-west Provinces was in excess of other residents there. Lieutenant-Colonel Giles pointed out that in reference to the cause there was one point in which the Bengali differed from all other civilised tropical inhabitants, inasmuch as he was the only man who went about in a tropical sun with a closely cropped bare head, added to which his complexion was not dark enough to do so with impunity.

Dr. H. MARCUS FERNANDO (Ceylon) stated that diabetes was very common amongst the educated classes of natives in Ceylon and was a disease due not to climatic or to racial conditions but to conditions of diet and habits of life. Europeans in Ceylon were no more prone to the disease than in Britain, whereas amongst the natives, professional men, and merchants, diabetes was quite common. In Ceylon the disease prevailed more amongst the Hindus than amongst Mahomedans and Singhalese, the last mentioned being the least affected. The causes assignable were (1) carbohydrate diet; (2) sedentary life; and (3) continuous application to work and no holidays. The disease seemed to be hereditary, to effect the overfed and obese, and to run in Ceylon the same course as they observed in Europe. Dyspepsia did not seem an early feature of the disease nor did the exposure of the head to the sun seem to play a prominent part in the etiology of the disease, for the Tamils went about with their heads bare, yet diabetes amongst them was very rare.

Mr. W. H. DE SILVA (Ceylon) said that ocular symptoms in diabetes in Ceylon corresponded closely with those met with in Europe. Diabetics were undoubtedly more prone to cataract, yet when the patient improved under treatment in Paisley and 19·5 in Perth. The 436 deaths in these towns showed a decrease of 43 from the number in the previous week, and included 52 which were referred to the principal epidemic diseases, against 66, 60, and 75 in the three preceding weeks. These 52 deaths were equal to an annual rate of 1·5 per 1000, which slightly exceeded the mean rate during the same period from the principal epidemic diseases in the 76 large English towns; they included 18 which were referred to whooping-cough, 15 to diarrhœa, 13 to "fever," four to measles, one to scarlet fever, and one to diphtheria, but not any to small-pox. The deaths from whooping-cough, which had been 12 and 30 in the two preceding weeks, declined again last week to 18, of which 10 occurred in Glasgow, four in Edinburgh, and two in Leith. The fatal cases of diarrhœa, which had been 21 and 22 in the two previous weeks, decreased to 15 during the week under notice, and included eight in Glasgow, three in Dundee, and two in Aberdeen. The deaths referred to different forms of "fever," which had been 15, 15, and 13 in the three preceding weeks, were again 13 last week; they included seven cases of cerebro-spinal meningitis in Glasgow, two in Edinburgh, and one in Paisley. The fatal cases of measles, which had been six in each of the two previous weeks, declined last week to four, of which two occurred in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 68 and 55 in the two preceding weeks, further decreased to 48 last week, and were 20 below the number in the corresponding period of last year. The causes of 15, or 3·4 per cent., of the deaths registered in the eight towns last week were not certified; in the 76 English towns the proportion of uncertified deaths did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 21·2, 18·0, and 15·7 per 1000 in the three preceding weeks, rose again to 17·8 per 1000 in the week ending August 17th. During the first seven weeks of the current quarter the death-rate has averaged 19·1 per 1000, the rates during the same period being 11·9 in London and 12·1 in Edinburgh. The 133 deaths of Dublin residents registered during the week under notice were 15 in excess of the number in the previous week, and included 17 which were referred to the principal epidemic diseases, against 12, 15, and 13 in the three preceding weeks; of these, seven resulted from measles, six from diarrhœa, three from whooping-cough, and one from "fever," but not any from small-pox, from scarlet fever, or from diphtheria. These 17 deaths were equal to an annual rate of 2·3 per 1000; the death-rate last week from the principal epidemic diseases did not exceed 1·4 in London and 1·2 in Edinburgh. The fatal cases of measles, which had been three, six, and five in the three preceding weeks, rose to seven last week. The deaths from diarrhœa, which had been four, three, and five in the three preceding weeks, further increased to six in the week under notice; while the fatal cases of whooping-cough numbered three, against four, four, and one in the three preceding weeks. The 133 deaths from all causes in Dublin last week included 36 of children under one year of age and 28 of persons aged upwards of 60 years; both these numbers were slightly in excess of the corresponding figures for the previous week. One death from violence and two inquest cases were registered; and 52, or 39·1 per cent., of the deaths in Dublin last week were not certified; the percentage of uncertified deaths in London did not exceed 0·2, while in Edinburgh the proportion was 1·3 per cent. The 101 deaths in Belfast included six which were attributed to cerebro-spinal fever.

VITAL STATISTICS OF LONDON DURING JULY, 1907.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 8·7 per 1000 of the population, estimated at 4,758,218 persons in the middle of the year; the rates in the three preceding months were 6·9, 7·1, and 7·2 per 1000 respectively. The lowest rates last month were recorded in the Cities of London and Westminster, and the boroughs of Hampstead, Chelsea, and Woolwich; and the highest rates in Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Deptford. No case of small-pox was notified in London during the month. The prevalence of scarlet fever showed a marked increase over that recorded in other recent months; this disease was proportionally most prevalent in Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, Deptford, and Woolwich. The Metropolitan Asylums hospitals contained 3578 scarlet fever patients at the end of last month, against 2586, 2777, and 2975 at the end of the three preceding months; the weekly admissions averaged 500, against 332, 368, and 390 in the three preceding months. Diphtheria also showed an increased prevalence as compared with the previous month; among the various metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Hammersmith, Poplar, Southwark, Bermondsey, and Greenwich There were 913 diphtheria patients in the Metropolitan Asylums hospitals at the end of last month, against 948, 933, and 806 at the end of the three preceding months; the weekly admissions averaged 140, against 119, 121 and 107 in the three preceding months. Enteric fever was again less prevalent than it had been in other recent months; this disease was proportionally most prevalent in Fulham, Stoke Newington, Hackney, Southwark, and Deptford. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 66, 47, and 57 at the end of the three preceding months, had declined again to 50 at the end of last month; the weekly admissions averaged nine, against 12, nine, and 13 in the three preceding months. Erysipelas was proportionally most prevalent in St. Pancras, Finsbury, Shoreditch, Stepney, Poplar, and Deptford. The 23 cases of puerperal fever notified during the month included three in Lambeth and in Camberwell, and two in Hammersmith, Fulham, Stepney, and Southwark. Of the 17 cases notified as cerebro-spinal fever, four belonged to Islington, three to Battersea, and two to Bermondsey.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the five weeks ending August 3rd the deaths of 5191 persons belonging to London were registered, equal to an annual rate of 11·4 per 1000; in the three preceding months the rates had been 15·8, 14·0, and 12·2 per 1000. The death-rates last month ranged from 6·8 in Hampstead, 8·3 in Lewisham, 8·5 in Woolwich, 8·6 in Stoke Newington, 9·2 in Greenwich, and 9·3 in Hammersmith, to 14·1 in Southwark, 14·4 in Finsbury and in Bermondsey, 14·7 in Poplar, 14·9 in Holborn, and 15·8 in Shoreditch. The 5191 deaths from all causes included 590 which were referred to the principal infectious diseases; of these, 219 resulted from measles, 71 from scarlet fever, 49 from diphtheria, 166 from whooping-cough, nine from enteric fever, 76 from diarrhœa, and none from small-pox, from typhus fever, or from ill-defined pyrexia; in addition to these 590 deaths there were three fatal cases of cerebro-spinal fever, including two in Battersea and one in Stepney. No death from any of the principal infectious diseases was recorded in the City of London; they caused the lowest rates in Paddington, the City of Westminster, Stoke Newington, Greenwich, Lewisham, and Woolwich; and the highest rates in Chelsea, Shoreditch, Bethnal Green, Poplar, Southwark, and Battersea. The 219 fatal cases of measles were 61 in excess of the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Chelsea, Hampstead, Islington, Shoreditch, Southwark, and Battersea. The 71 deaths from scarlet fever were 28 above the corrected average number; the greatest proportional mortality from this disease was recorded in Hackney, Bethnal Green, Stepney, Bermondsey, and Battersea. The 49 fatal cases of diphtheria showed a decline of 12 from the average number in the corresponding period of the five preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Kensington, Poplar, Southwark, Battersea, and Camberwell. The 166 deaths from whooping-cough were 46 in excess of the corrected average number; the highest death-rates from this disease were recorded in Hammersmith, Fulham Chelsea, Shoreditch, Bethnal Green, and Poplar. Only nine deaths from "fever" were registered last month, against an average of 38 in the corresponding period of the five preceding years; of these nine deaths

THE LANCET.

LONDON: SATURDAY, AUGUST 24, 1907.

The Plague in India: The King's Message.

No people in the world are moved more readily by kindly feelings displayed towards them than are the people of India. It is because of this that we venture to say that the message concerning plague which His Majesty the King-Emperor has recently addressed through his Viceroy to his Indian subjects will not only be received with profound satisfaction and gratitude throughout our Eastern Empire but will also exercise a potent influence on the success of future preventive measures. King Edward expresses his heartfelt sympathy with the people of India in their sufferings, and he makes known the deep emotion he feels when thinking of the misery that has been borne with such silent patience in all those stricken homes. He adds that it is his earnest hope and prayer that the further measures now being prepared may be crowned with merciful success. The message will bring fresh hope and courage to those who have suffered so long, and who may be excused if they have now fallen into a state of despair; it will encourage all those who, with inadequate means at their disposal, have nobly striven to do their best to combat this scourge; it will be an impetus to further exertions; and it will arouse the Government of India to a quickened sense of responsibility and of the importance and urgency of doing everything in their power to check the ravages of plague.

That such a stimulus may be needed is evident from the fact that it has taken two years for the Government of India to consider the proposals put forward in the Memorandum on Plague which was presented by the Royal College of Physicians of London to Mr. Brodrick at a deputation received on July 24th, 1905—since which time 1,500,000 people at least have died from plague in India. Almost coincident with the publication of the King's letter in the daily press the official correspondence regarding the measures being taken in India for the prevention of the plague was presented to both Houses of Parliament, the correspondence having its origin in the Memorandum of the Royal College of Physicians of London. It may be remembered that the scheme formulated by a committee of the College provided for a special medical and sanitary organisation which should deal with plague in selected localities. The staff of this service, it was suggested, should consist of officers of the Indian Medical Service and physicians brought out from England, having under their control male and female native medical assistants—the subordinate staff to be gradually increased in numbers and trained to greater responsibilities. The whole service, it was proposed, should work under the direction of a special head-quarters department and be divided into three sections: (1) an intelligence branch; (2) a sanitary branch working at practical measures on the scene of an outbreak; and (3) a bacteriological branch. The scheme was submitted by Mr. Brodrick on August 18th, 1905, to the Government of India and the views of that Government were invited. These views have now crystallised in the form of a Blue-book which contains some apology for the extraordinary delay in procedure. The memorandum of the College was received, the Government says, at a critical time in the history of plague administration when all suggestions were most welcome, but, unfortunately, it did not appear to contain anything with which the Government was unacquainted, while it revealed a lack of knowledge on the part of the signatories in respect of plague administration in India. With regard to the innovations in administration suggested by the memorandum, replies were deferred until the views of the various local administrations of India could be obtained. Accordingly the local governments were consulted in May, 1906, and the letter covering their replies, and forwarding them for Mr. Morley's information, is dated May, 1907, although most of the local governments appear to have been prompt in their replies. The net result of the local views is that suitable organisations for coping with the epidemic of plague in India already exist, although the executive may call for strengthening, while the general sanitary service needs development. The Government of India, informed by the opinions of the local governments, accordingly decides that in measures for the prevention of plague trust must be placed, *at any rate for the present*, upon improved sanitation in towns and upon the coöperation of the people in such measures as the evacuation of villages and the destruction of rats. The Government of India sees no virtue in the memorandum of the Royal College of Physicians of London.

To the Government of India Mr. Morley has made a significant reply, for while recognising the admission that the general sanitary service of India needs development, he asks for the specific proposals of the Government in this direction, noting that the measures now relied upon are avowedly only temporary. He recalls the fact that plague has been fatally active in India over 11 years, pointing out "that the number of victims exceed five and a quarter millions, that its virulence is unabated and its progress uncontrolled," circumstances which he considers "necessarily give rise to doubts as to whether everything that can be done has been done by the responsible authority, and whether the last word of medical science and administrative skill has really been said." The importance of the attitude of the Government of India to the people in regard to preventive measures has not escaped the attention of Mr. Morley and we are glad to see him so decided on what that attitude should be. The view that preventive measures depend for their success upon the coöperation of the people is interpreted by Mr. Morley in a very different manner from that which has governed action in India. It is accepted by him as merely defining the conditions of success and not as a reason for abdicating responsibility. Popular sentiment does not remove the obligations which still rest on the Government to endeavour to improve the quality of hygienic measures and to win acceptance for them by skilled two belonged to Stepney and one to each of seven other boroughs. The deaths from diarrhœa numbered 76 last month, against an average of 555 in the corresponding period of the five years 1902–06; the greatest proportional mortality from this disease occurred in Fulham, the City of Westminster, Islington, Shoreditch, Southwark, and Lambeth. In conclusion, it may be stated that the aggregate mortality from the principal infectious diseases in London last month was 30 per cent. below the average.

Infant mortality, measured by the proportion of deaths under one year of age to registered births, was equal to 83 per 1000. No death at this age was recorded in the City of London, while among the metropolitan boroughs the lowest rates of infant mortality were recorded in Hammersmith, St. Marylebone, Finsbury, and Lewisham; and the highest rates in Kensington, Chelsea, Stoke Newington, Shoreditch, Bethnal Green, and Poplar.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Jerome Barry has been placed on the Retired List.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants are confirmed in that rank: Hugh E. Gotelee, John H. Spencer, Benjamin Johnson, William E. C. Lunn, Arthur H. Jacob, Clarence H. Denyer, Alexander D. Fraser, Archer Fortescue, Geoffrey Carlisle, Howard G. Gibson, Stephen Field, Frederick H. M. Chapman, Henry M. J. Perry, John L. Wood, Frederick T. Turner, Michael P. Leahy, William G. Aviss, John E. M. Boyd, Donald F. Mackenzie, Richard D. O'Connor, Owen R. McEwen, Malcolm C. Wilson, John du P. Langrishe, John C. Hart, Thomas H. Scott, Gerald F. Rudkin, Leopold A. A. Andrews, John H. Gurley, Alfred C. Elliott, William B. Purdon, Francis Casement, Edward M. Middleton, Vincent T. Carruthers, and Harold W. Farebrother.

Captain H. G F. Stallard has joined at Aldershot for duty at the depôt and school of instruction and Captain A. H. Stafford and Lieutenant H. E. Gotelee have been posted to the Cambridge Hospital for duty. Lieutenant W. B. Purdon and Lieutenant J. C. Hart have also joined at Aldershot and been posted to the Connaught Hospital for duty.

Colonel Arthur W. P. Inman is placed on temporary half-pay on account of ill health (dated August 14th, 1907).

VOLUNTEER CORPS.

Rifle: 3rd Volunteer Battalion the South Wales Borderers: Surgeon-Lieutenant-Colonel J. R. Essex is granted the honorary rank of Surgeon-Colonel (dated June 26th, 1907). 2nd Volunteer Battalion the King's (Shropshire Light Infantry): Charles Botterill Baxter to be Surgeon-Lieutenant (dated July 1st, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

4th or City of London Bearer Company: Captain A. C. Tunstall to be Major (dated July 25th, 1907).

DEATHS IN THE SERVICES.

Major T. W. A Fullerton, I.M.S., Bengal, at Lucknow, on August 15th. He entered the service in 1895 and at the time of his death, which occurred from blood poisoning, he was surgeon to the hospital at Bahraich. He held the Kaisar-i-Hind gold medal for public service in India and two medals for service in two frontier campaigns.

Major H. F. Whitchurch, I.M.S., V.C., at Dharmsala, Punjab, India, on August 16th, at the age of 41 years. Major Whitchurch took part in the Lushai Expedition, including the relief of Changsil and Aigal (medal with clasp) and in the operations in Chitral in 1895 (mentioned in despatches and awarded medal with clasp and the Victoria Cross). The act of conspicuous bravery which obtained for him this distinction is officially described as follows. "During the sortie from Chitral Fort at the commencement of the siege Surgeon-Captain Whitchurch went to the assistance of Captain Baird, 24th Bengal Infantry, who was mortally wounded, and brought him back to the fort under a heavy fire from the enemy. Captain Baird was on the right of the fighting line and had only a small party of Gurkhas and men of the 4th Kashmir Rifles. He was wounded on the heights at a distance of a mile and a half from the fort. When Surgeon Captain Whitchurch proceeded to his rescue the enemy in great strength had broken through the fighting line; darkness had set in, and Captain Baird, Surgeon-Captain Whitchurch, and the sepoys were completely isolated from assistance. Captain Baird was placed in a dooly by Surgeon-Captain Whitchurch, and the party then attempted to return to the fort. The Gurkhas bravely clung to the dooly until three were killed and a fourth was severely wounded. Surgeon-Captain Whitchurch then put Captain Baird upon his back and carried him some distance with heroic courage and resolution. The little party kept diminishing in numbers, being fired at the whole way. On one or two occasions Surgeon-Captain Whitchurch was obliged to charge walls, from behind which the enemy kept up an incessant fire. At one place particularly the whole party was in imminent danger of being cut up, having been surrounded by the enemy. Surgeon-Captain Whitchurch gallantly rushed the position and eventually succeeded in getting Captain Baird and the sepoys into the fort. Nearly all the party were wounded, Captain Baird receiving two additional wounds before reaching the fort." Major Whitchurch was also engaged in the campaign on the North-West Frontier of India in 1897–98, taking part in the defence of Malakand, the relief of Chakdara, the action at Landakai, and the operations in Bajaur and in the Mamund country (mentioned in despatches and two clasps). He also took part in the operations in China in 1900 (mentioned in despatches and awarded medal with clasp).

MOIR MEMORIAL FUND.

The following gentlemen have, at the invitation of the council of the Medical College, Calcutta, agreed to serve as members of a committee, with power to add to its number, for the purpose of raising a memorial to the late Major D. M. Moir, I.M.S., professor of anatomy at the Medical College, Calcutta, who died from septicæmia contracted in the execution of his public duties. Subscriptions are invited from his friends and admirers and may be sent to the treasurer. It is hoped that sufficient money will be received to found a prize or to endow a bed, after providing for a tablet and portrait in the College Hospital. Lieutenant-Colonel F. J. Drury, I.M.S., President; Major F. J. Maynard, I.M.S; Major R. Bird, I.M.S., C.I.E.; Major C. R. Stevens, I M S.; Major W. J. Buchanan, I.M.S.; Rai Bahadur Dr. Koylash Chandra Bose, C.I.E.; Rai Bahadur Dr. Devendra Nath Roy; Dr. Suresh P. Sarbadhicary, treasurer, 79/1, Ahmerst-street, Calcutta; Dr. Dwijendra Nath Moitra; Assistant-Surgeon Jotish Ch. Mustafi; and Captain F. P. Connor, I.M.S., and Rai Bahadur Dr. Hira Lal Basu, honorary secretaries, Medical College.

THE NEW DRESSING PACKET FOR THE GERMAN ARMY.

A new packet containing material for the first dressing of a wounded soldier has been served out in the German army. It weighs 25 grammes and measures, in centimetres, 7·4 by 4·5 by 1·9. The envelope, made of impermeable linen, is secured by a knotted string which has to be severed before the packet can be opened. Instructions to this effect are printed on the outside. Each envelope incloses a linen bandage impregnated with corrosive sublimate, four metres long by seven centimetres wide. It is readily divisible into three segments, and midway on each segment there is affixed a compress or pad for application to the wound. The bandage itself is white or grey, but the pads are red. On the inner flap of the envelope there are the following instructions:—

> On no account must the red pad or the wound be touched by the fingers of the operator. Taking hold of the segment of bandage with both hands at the points marked "here" he should stretch it firmly and apply the pad accurately over the wounded part, finishing the process by winding the two ends of the bandage round the injured site where they should be secured by a knot.

A new diagnosis card has also been issued for use on the field of battle. It is about 5¼ inches long by 3½ inches broad, and is meant to be attached to "the second button of the wounded man's tunic, cloak, or shirt." Each card has two red bands which can easily be torn off. If the patient can walk the bands must be removed; should he require transport one band must be left, but should he be considered "non-transportable" both the bands must remain intact. In one side of the card spaces are left for replies to the following questions: Name, rank, and corps? Wound or disease? Treatment given? Elastic band or tube, where applied? Stimulants administered, time, amount? On the other side the surgeon should add any further particulars he may deem necessary and sign his name. The cards are solely for the use of medical officers.

authorities of Trinidad and Barbados. Small-pox had been prevalent in the latter island and subsequently an outbreak of disease occurred in the former which was declared not to be small-pox but an "eruptive fever" which was termed "epidemic varioloid varicella." Communications which passed between the governors of the two islands resulted in the despatch to Trinidad of Mr. J. F. E. BRIDGER who had been in charge of the small-pox hospital upon Pelican Island during the epidemic in Barbados. Mr. BRIDGER conducted his duties in a most thorough and scientific manner and came to the conclusion that the epidemic in Trinidad was "small-pox of a very mild type." This decision was not then accepted by the Medical Board of Trinidad. At the time we endeavoured to reconcile the conflicting opinions and pointed out that for a few years a similar mild eruptive varioloid disease had been extending over Canada and the United States, and we suggested that from the epidemiological standpoint it was highly probable that the disease, whatever it might be called, was the same in all these places. Subsequently, with a sense of relief, we were enabled to record a distinct change in the attitude of the Trinidad authorities. We received a copy of a leaflet issued by the medical officer of health of Trinidad headed "The Prevailing Epidemic: How to Prevent its Spreading," which compelled the conviction that the disease was recognised as being small-pox, although that dreaded word did not appear in print. We gave our reasons for arriving at that conclusion.

We have now received a colonial Blue-book issued by the Central Quarantine Authority for the West Indies, giving an account of the proceedings at meetings held at Bridgetown, Barbados, on June 11th and 12th last. We may here explain that by a scheme recommended by the Quarantine Conference of 1904, and recently adopted at the instance of the Secretary of State for the Colonies by the various colonial Governments which were signatories to the Convention, the Central Quarantine Authority was to meet once at least in three years or at any time at the request of two parties to the Convention. The recurrence of some cases of "eruptive fever" (similar to those which had occurred in Trinidad) and the outbreak of yellow fever in Trinidad had caused several questions under the Convention to arise between Grenada and Barbados on the one hand, and between Trinidad and Grenada and Barbados on the other. The meeting in June was accordingly summoned, and delegates from Trinidad, British Guiana, the Windward Islands, the Leeward Islands, and Barbados attended, with the Hon. W. K. CHANDLER, LL.D., C.M.G., as president. Many subjects of interest were discussed and the conclusions arrived at will doubtless be of lasting benefit in matters relating to infectious diseases in the islands concerned. We are concerned, however, at the present time with the epidemics of "eruptive fever" to which we have referred. The remarks on these outbreaks as reproduced in the Blue-book are brief but emphatic. The meeting considered and unanimously adopted the following decision: "That the disease which has within recent years been prevalent in Grenada and Trinidad, and there known by the name of 'eruptive fever,' is small-pox." We receive this conclusion with a considerable amount of satisfaction, as a reference to our previous views on the subject will prove that we strongly insisted upon this diagnosis as the correct one. To Mr. BRIDGER great credit is due for the firm attitude which he assumed after his visit to Trinidad at the time of the early epidemics. A medical heresy which he detected has been refuted and epidemiologists will welcome the announcement that the "new" epidemic disease which was said to have occurred in Trinidad in 1902–03 is now fully recognised to have been small-pox.

The reluctance of the authorities of Trinidad to acknowledge the existence of small-pox in the island, with the consequent harm to commercial enterprises, can well be imagined, but no good ever came of the policy of concealment, though it is eternally attempted in these situations by Governments no less than by municipalities and private individuals. The subsequent and somewhat tardy announcement of the Central Quarantine Authority for the West Indies, however, is worthy of all praise, as disposing of any doubt as to the real nature of the disease which was locally designated "eruptive fever." The whole history of the epidemic again proves what has now been so often experienced, the difficulties which may arise in the diagnosis of small-pox. As is well known, the distinction from varicella is often most difficult, and unless suitable precautions are adopted in doubtful cases widespread and deplorable results may follow. In the Blue-book no full account of the discussions is recorded; perhaps, as purely technical matters were involved, this was a wise procedure, but there were several points which required elucidation. For example, in the earlier stages of the controversy it was suggested that the epidemic disease in Trinidad was uninfluenced by vaccination, therefore it could not be small-pox. As we pointed out at the time, Mr. BRIDGER adduced evidence to the contrary, and it would have been interesting to know now whether vaccination was generally adopted after Mr. BRIDGER's report and whether this had a notable effect on the spread of the epidemic. The medical officer of Trinidad, during the time of the early epidemic, recommended all persons not thus protected to be vaccinated, and we should have liked to hear a summary of what was done and what resulted. Mr. BRIDGER was subjected to much criticism at the time for daring to call the disease small-pox, but the decision arrived at by the Central Quarantine Authority amply bears out his contentions, and the courage which he exhibited in stating his unpopular opinion will win him great credit for independence as well as acumen.

The Connexion between Recruiting and the National Health.

THE statistics of recruiting and the general observations of the officers engaged in that important duty can be regarded as supplying a valuable link between the sciences of medicine and anthropology. As civilisation advances and knowledge and experience increase it will become clearer to all how paramount an object of interest to the nation as a whole is the health of every individual member of the nation. While, on the one hand, in hospitals and in private practice, the different types of accident, deformity, and disease present themselves daily to the physician, the surgeon, and the specialist, on the other hand, the different types of essential before we can move in the matter—namely, voltage, ampèrage, wattage, time, and frequency. I have already referred to voltage, ampèrage, and frequency, and I have generally, if not always, stated the time; but why wattage as a fifth factor if we already have the voltage and the ampèrage? and what does Dr. Bowie mean by saying that wattage must be based on ampèrage since it is the product of voltage and ampèrage? Again, in auto-condensation, which is the mode of application, I have been considering what authority has Dr. Bowie for saying that little or no current passes through the body, though an apparently high current was being registered in the milliampèrometer in series with the body? What means does he suggest for testing this? And let me remind him that no one has said that any current passes through the body. The current is not passing through but passing into and out of the body, and I have shown in my paper that the current loses force and quantity on its way into the body. It is a current in the meter but a capacity in the body. He evidently finds it difficult to get low-tension phenomena out of his mind. We are not dealing with closed circuits here. This very error, however, ought to have prevented him from saying that a body through which a current is passing may be getting almost no current regardless of the current which a milliampèrometer in series with it was registering. When I come to his remarks on the drop of potential observed by me when carrying out my experiments I at first hope that we are now on common ground; and, since I attach considerable importance to this part of my thesis, I should have been pleased to get from him some practical criticism of it. Instead of this, however, what he gives me is a mere theoretical contradiction. So I do join issue with him when he "respectfully submits that this is impossible." Is it possible that he has made this statement without having tried the experiment for himself?

Dr. Bowie states that "no relation exists between the resistance of the body and the tension of the current on the spinthermeter." I have stated as a fact that, whilst this auto-condensation current is being applied, the difference of potential between, say, the hand and the axilla may exceed the equivalent of a spark-gap of two millimetres. Has Dr. Bowie tested this which I have declared to be a fact? If not, he surely might have done so and given us the benefit of his experience. That this difference of potential does not arise from ohmic resistance alone is, I think, true; but I should like to have Dr. Bowie's explanation of it if "resistance bears no relation to the potential difference." Does he think this resistance is a small matter? I have measured it with dry metallic electrodes as used in auto-condensation and found it to be vastly greater than I had suspected to be possible. I fear that much of what follows in Dr. Bowie's letter is too involved for me to be able to follow it. Either he has failed to grasp my meaning or I fail to grasp his. Let me say again, however, that I would rather he had stated not what he thought should be but what he really found to be the case. This is especially to be desired where he disputes the accuracy of my statement as to the fall of potential due to the passage of the current along a copper wire 25 feet long and of low ohmic resistance. He fails to see that mere ohmic resistance, unless enormous in amount, exercises practically no control on these high potential oscillations. Whether distance or the necessary bending of the wire on itself on account of the limited space in my room is the cause of the fall of potential I know not—possibly both may be; but certainly ohmic resistance has here nothing to do with it. Surely Dr. Bowie fails to see that he is giving himself away when he says: "Further, it is necessary that the electrodes be kept at the normal temperature of the body, otherwise no accurate records can be made, and this is particularly the case when observations are being taken regarding the increase of temperature due to these currents"; for if the electrodes had first been warmed to the temperature of the hands the rise in the temperature of the forearm would have been just so much greater, and thus my contention would have been strengthened. My object in recording the temperature of the room and delaying the application of the current in these thermic experiments till from 30 to 40 minutes had elapsed after the patient had been placed on the couch was to secure as much accuracy as possible. Dr. Bowie attempts to reply to my question No. 1 in a very offhand manner. But when he says that his "answer to this is, as the voltage is increased a corresponding fall in current will take place," he is evidently failing to note what I said on this point—namely, that I found from experiment that "the same quantity of current is obtainable from the same apparatus by a different arrangement of solenoid and spark gap, though there might be a different amount of potential difference to earth."

If Dr. Bowie is prepared to apply to the body 400 watts, made up of five ampères at a voltage of 80, all I have to say is that I should not like to be the victim of this experiment. But how, I may ask, is he to obtain a current of five ampères through the body from a voltage of 80 or 100, since, as in the Apostoli treatment, it is difficult to obtain a twentieth part of this current from a voltage not much less? I am thus prepared to challenge his statement, though I am not prepared to have my "body subjected" to the trial, even with the reward of setting the question at rest. Finally, is Dr. Bowie willing to join the scientific investigation committee which I have proposed and which he says he approves of? I trust he is—that is, of course, on the understanding that he has already done some work in high-frequency treatment. In that event some real gain may come out of it.

I am, Sirs, yours faithfully,
SAMUEL SLOAN.

Glasgow, August 10th, 1907.

NATIONAL LENDING LIBRARY FOR THE BLIND.

To the Editors of THE LANCET.

SIRS,—Will you kindly insert an appeal on behalf of the above most useful and much needed institution as it is in urgent need of funds to carry on the work? It is practically the only lending library for the blind for the whole of Great Britain. There are 900 direct readers, and about 900 more are reached through various institutions, to which books are sent. There are 40,000 blind persons in Britain! These could all be reached had the library a larger income. Each volume costs 15*s.* to produce. Owing to the bulkiness of the volumes, as a result of the raised type, the space needed for storage is great, and a new building is absolutely required in which the 8500 volumes now in stock can be properly arranged, quickly found, and despatched through the post at "special rates," thanks to the kindness of the Hon. Sydney Buxton, Postmaster-General. The books are printed, some in the "Moon type," the rest in the "Braille type." An annual subscription of two guineas entitles a subscriber to nominate a poor reader who without the solace of books leads a sadly pitiful life in his sightless condition. We need £200 per annum more in subscriptions to carry on the work and far more than that sum in donations to enlarge the necessary premises and extend the usefulness of the lending library. Would that some wealthy man or woman might be moved by pity to purchase a site, build really suitable premises, and provide a fund for the maintenance of the building. The library was opened in 1882 by the late Mrs. Dow and the late Miss Martha Arnold, and was incorporated as a "charitable institution" in 1898. H.R.H. Princess Louise, Duchess of Argyll, is President, the patrons are the Bishop of London, the Bishop of Stepney, the Bishop of Southwark, the Duchess of Marlborough, the Earl of Kilmorey, and other distinguished persons. Full details concerning the library may be obtained from the Secretary, Miss E. W. Austin, National Lending Library for the Blind, 125, Queen's-road, Bayswater, W., to whom cheques and postal orders may be sent.

I am, Sirs, your obliged servant,
JANE B. WHITE.

August 19th, 1907.

A CASE OF PYREXIA OF UNCERTAIN ORIGIN.

To the Editors of THE LANCET.

SIRS,—Can you find room for the account of the following case in order that members of the profession may offer suggestions as regards diagnosis?

A female child, three and a half years old, was brought to my consulting-room on the morning of August 6th on account of "feverishness" during the night. I examined the case carefully and, apart from a temperature of 100° F., could find no physical signs of disease in any of the organs. The throat was clear but the bowels were confined. I prescribed grain doses of calomel in the form of sweets and saw the patient again in the evening of the same day. The temperature had then risen to 101°. I gave her a saline mixture and saw her again two mornings later (August 8th), when inflammatory changes in the appendix. Partly these bodies accomplish this by blocking the outlet and favouring the accumulation of mucus within the appendix. The increased tension thus produced in itself assists the passage of microbes into and through the mucous membrane and the other coats of the appendix, but it also damages the mucous membrane and thus lessens its resisting power. Further by inflicting injury on the lining membrane of the appendix these bodies assist in producing appendicitis. Before discussing the nature of these appendical bodies it is well to make clear the fact that the presence of one of these bodies is by *no means* essential to the production of an attack of appendicitis; in very many cases no included body is found in the appendix and even when it is there it is not rarely probable that it has not assisted in the causation of the appendicitis. Moreover, it is clear from our present knowledge that, though the stenosis which prevents the escape of an appendical body may be the result of the irritation produced by that body, a stenosis may occur from any attack of appendicitis, due to any cause whatever, and without the presence of an appendical body. In the present issue of THE LANCET are three papers bearing on the subject of the nature of the bodies found in the appendix. When the diseases of this organ first attracted the attention of the medical public it was believed that the majority of these bodies were "foreign bodies" in the sense that they were thought to have been taken in by the mouth. Many of them were of the size and shape of cherry stones, others resembled apple pips, and even when examined more carefully the stratification which was seen was thought to support the theory that they were seeds. Microscopic and chemical examination have shown, however, that the vast majority of these "foreign bodies" are nothing more than masses of fæcal material bound together with inspissated mucus. When the appendix is healthy it is possible that small fæcal particles may enter the organ for a time and then be carried out with the flow of the secretion of the appendix; but if at any time the presence of a minute fæcal mass should coincide with some predisposing factor, some temporary swelling of the mucous membrane near the orifice, then the imprisoned particle grows by the deposition on it of more fæcal material and is cemented with the morbid mucus poured out by the irritated walls. Not only, however, do these fæcal conglomerations mimic "foreign bodies"—that is to say, substances introduced from without—but they also imitate structures formed elsewhere in the body. Sometimes, though rarely, a number of facetted "calculi" are found in an appendix; in colour, in shape, and in appearance they are almost indistinguishable from biliary calculi; and it is certain that some of the cases in which gall-stones have been described as occurring in the appendix have been instances of facetted appendical concretions. The only valid test is the chemical, for if cholesterin and bile pigments are shown to be present the calculi may be claimed as gall-stones. Judged by this test true biliary calculi do very rarely occur in the appendix. Dr. D. T. Barry of Cork has contributed a paper to this issue of THE LANCET in which he describes a case where *four* small facetted stones were found in the appendix. They closely resembled biliary calculi, but when tested for cholesterin and for bile salts only negative results were obtained, and they were found to consist chiefly of calcium phosphate with a little organic matter. But true foreign bodies do occur in the appendix, and a paper, also in this number of THE LANCET, by Dr. W. Hal Barnett and Dr. J. W. Scott Macfie, describes a case in which a clove was found in a vermiform appendix which was the sole viscus in an inguinal hernia. The clove was well preserved and probably this was owing to its essential oil. The most important, however, of the three contributions which we have mentioned is by Mr. W. H. Battle. He points out that many fæcal concretions in the appendix have formed about a foreign body as a nucleus. This nucleus may be sometimes as big as a pin but it may be a minute particle. Of what does it usually consist? Mr. Battle maintains that there has been a real increase in the frequency of appendicitis; the older physicians did not have so many cases as we see now; it was not merely a want of observation; they were careful observers and if the condition had been even half as frequent as it is at present they would have observed it. Dr. Samuel Fenwick found only 19 cases of disease of the appendix in the post-mortem records of the London Hospital in a period of 40 years ending 1884. Several theories have been suggested to account for the real and enormous increase which has occurred, and after discussing some of the suggestions Mr. Battle brings forth the idea that minute particles of iron are the real cause. He shows that the great increase of appendicitis first occurred in America and at a time when steel or iron rollers had been recently introduced for grinding flour. The increase of appendicitis occurred first in the towns where the rolled flour was first used; then it spread to the villages, and lastly to the negroes who had earlier escaped, and this spread corresponded with the spread of the use of rolled flour. The invasion of this country followed, when the lower cost of American flour made it almost impossible for any extensive grinding of flour to take place in this country. If this explanation be correct we should expect to find iron particles in the centre of appendical concretions, and so we do. Mr. Battle recounts a typical case of appendicitis in which at the operation a concretion was found and in its centre was an irregular fragment of iron. It is well worth while to examine into the truth of this suggestion. The detection of metallic iron is easy; the magnet is of itself sufficient, but if any more were needed heating the concretion with dilute hydrochloric acid would soon furnish a solution to which the ordinary tests for iron could be applied. We are inclined to think there may be a good foundation for Mr. Battle's theory, and if examination shall prove its correctness in any appreciable number of cases we should be in a position to suggest precautions which might mitigate the frequency of appendicitis.

THE TRIPPER'S LEAVINGS.

THE excursionist who litters a grassy glade with greasy paper, who cuts his name on a venerable monument, or who pulls up the lilies on some lovely sheet of water is an objectionable nuisance whose education, not always that of the board school, has failed to teach him decent behaviour. He is, moreover, a person not likely to be deterred by any consideration for others from his malpractices, even if it be pointed out to him that his conduct not only annoys persons who are strangers to him but is actually a cause of danger to them. The waste-paper referred to once enwrapped the solids of an *al fresco* meal, and it seems generally to be made as conspicuous as possible by those who abandon it. By a strange perversity such trippers, when they have finished the liquor which they have brought with them, abandon their glass bottles in a surreptitious manner so that they become traps to injure the unwary, having previously satisfied their love of useless destruction by breaking them, using them as missiles or targets. Sometimes the fragments lie on the road where they can be seen and avoided, at others they are hidden in long grass by the wayside. When there is water at hand the bottles are generally thrown into it in order to be broken with stones as they bob up and down. The water may be the sea near a favourite beach, and every holiday time in crowded watering-places accidents occur from this disgusting practice, children and others finding their holiday old work and surroundings and is at the present time doing well. In private practice it is difficult to treat chronic alcoholism on these lines because the mental advantages which result from the surroundings of a special home are an essential factor in bringing about the desired results.

The following statement appeared in a medical journal which I fully confirm: "That no treatment by drugs alone can be expected to yield permanent results, and in every case the general condition of the patient must be treated by general means, by simple dietry, by tonics, and by treatment of any physical lesion, while his mental and moral fibre is built up by judicious management and sympathetic influences." I am, Sirs, yours faithfully,

J. M. G. BREMNER, M.B. Aberd.

Norwich.

A CASE OF SUPERNUMERARY DIGITS.

To the Editors of THE LANCET.

SIRS,—The report of a case in THE LANCET of July 20th by Dr. W. H. W. Attlee recalls a case under me in 1902. In a newly born male infant I found that there was an extra little toe on each foot just as perfectly formed as the toe which rightfully belonged there and growing from a point over the metatarso-phalangeal joint. On the left hand was a perfectly formed little finger growing from a point on the ulnar side over the metacarpo-phalangeal joint, while on the right hand, in a similar position, was a jelly-like mass hanging by a mere thread of tissue which was undoubtedly intending to become a perfect digit at some time. I removed this latter mass of tissue by a mere twisting of its small pedicle. But although this was interesting enough I was astonished to find that of four other children in the home, two girls and two boys, each of the boys had an extra little toe on each foot and had been allowed to grow up to that date without any interference with these extra digits. There were no extra digits on their hands and the girls had no deformity whatever. Neither the father nor the mother was deformed in any way, nor were they related in any way before marriage.

I am, Sirs, yours faithfully,

CHLOROFORM ADMINISTRATION: THE "OPEN METHOD" v. APPARATUS.

To the Editors of THE LANCET.

SIRS,—In the discussion upon chloroform administration at the British Association meeting at Leicester there are two points upon which I should like to express dissent. First, Is not the danger of an under dose of chloroform a dangerous position to adopt? The explanation which Dr. Hewitt gave amounted to the fact that irregular and obstructive breathing occurred, but is not this seen in many cases in the first stage, to be met by increased caution, anxiety, call it what you will? Secondly, with regard to the "open method." Chloroform administration is so entirely one of judgment. Each case has to be treated upon its own merits. Cases differ so much in their susceptibility. The patient, not the apparatus, should be the only thing observed. With apparatus a certain percentage of chloroform to a patient, whose peculiarities, &c., are very largely an unknown quantity; with the open method an uncertain percentage is given. Directly the patient is found to be "going under" too quickly, or to present unfavourable symptoms, and when he is sufficiently under chloroform, the towel or flannel is at once removed from the patient's face and only pure air inspired; this, for quite a short time, or longer, according to the judgment of the administrator.

I am, Sirs, yours faithfully,

HENRY W. KING.

Chester, August 12th, 1907.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Launceston (Cornwall) Board of Guardians and Vaccination Fees.

AT a meeting of the Launceston board of guardians, held on August 12th, it was reported that the sub-committee which had been appointed to consider the question of the vaccination fees had conferred with the public vaccinators upon the subject, but the medical men were unanimous in declining to accept the fee of *3s. 6d.* offered by the guardians. After some discussion it was decided that the public vaccinators, if they still refused to accept the reduced fees, should be given 28 days' notice to terminate their contracts.

The Sewage of Bath.

In a report to the Bath sewage disposal committee Dr. H. Maclean Wilson (chief inspector of the West Riding Rivers Board) expressed the opinion that the question of sewage disposal in Bath offers no special difficulty, as the sewage must be pumped, and can easily be raised to such a level as will permit of any method of treatment. The report adds that the proposed site at Saltford, about midway between Bristol and Bath, is in most respects an excellent one for sewage works, and the works would probably be less costly than in many cases, because of the availability of materials and the ease of carriage to the site.

The Chippenham Board of Guardians and the Local Government Board.

At a meeting of the Chippenham board of guardians held on August 14th it was reported that the Local Government Board had written stating that after further consideration it must adhere to its previous decision, that as there was now a qualified medical practitioner residing in the district it could not consent to the continued employment of a non-resident medical officer beyond Dec. 25th next.

Proposed Cottage Hospital for Neath.

When a proposal was made about four years ago to establish a cottage hospital in Neath the scheme was opposed on the ground that the needs of the district were fully served by the hospital at Swansea. This view is not held by so many of the inhabitants of the town as was formerly the case, so that there is every possibility of a small hospital being established in Neath. In 1904 a sum of £2000 was given towards a hospital fund, one half to be used for building and the remainder to be invested. A further £300 have been subscribed and there ought to be no difficulty in a town of 15,000 inhabitants in obtaining the amount necessary to erect a building to suffice for, say, six patients. Wherever similar institutions have been established in other industrial centres in South Wales their usefulness has at once been appreciated and funds for their support have been readily obtained.

Illegitimacy in the Rhondda Valleys.

In his recently issued annual report the medical officer of health of the Rhondda valleys (Dr J. D. Jenkins) gives the amount of illegitimacy as it should be stated—namely, in proportion to the number of unmarried and widowed women at conceptive ages. There were 101 illegitimate births in the district during 1906, a number equal to 10·5 per 1000 unmarried women and widows living between 15 and 45 years. The proportion in England and Wales in 1905 was 8·2 per 1000. The infantile mortality rate during 1906 in the Rhondda was equal to 327 per 1000 illegitimate births compared with 171 per 1000 in the case of legitimate births and deaths.

Overcrowded and Insanitary Pembrokeshire School.

Instances of overcrowding in some of the public elementary schools in South Wales have been frequently published, but it is to be hoped that the conditions reported by a committee of the Pembrokeshire Education Authority as having been found in a school at Haking, near Haverfordwest, do not exist in many other schools. The average attendance was 175, but there was seating accommodation for only 108, so that many of the children had no desks or seats and had to sit on the floor. There was no room for the classes to stand and the five teachers taught in the sound of each other's voices. The sanitary offices were said to be in a filthy condition and the walls of the school rooms were so damp that the inside covering was peeling off.

Medical Officer of Health of Monmouthshire.

The Monmouthshire county council has at last decided to appoint a county medical officer of health. At the meeting of the council at which this decision was arrived at it was resolved to ask the Local Government Board not to press for the appointment of a joint medical officer of health for certain colliery districts in the western part of the county, and it was further decided not to make the appointment of a county officer until the decision of the Board on this question had been received. There was an evident disposition upon of the use of bacteriology as a preventive measure in relation to disease, the prevention of syphilis as a national evil, the housing question, and the securing of the necessary powers and funds to carry out the requirements in respect of the foregoing matters and all other questions relating to public health. An executive committee was appointed with power to arrange for the conference in question to be held in London in October or early in the winter and to invite representatives from Scotland and Ireland to the conference. We gave our support to this scheme at its inception as a definite endeavour to promote the establishment of a properly organised public health service such as in other countries is represented in the Cabinet. The recognition of the aims of the conference by speedy legislation does not appear to us to be very probable, but the thanks of the community will be due to those who are succeeding in making a public question of a national health authority. We consider that the present coöperation is setting to work in the right way to win notice in the proper quarters.

THE DIRTY WATER-BOTTLE.

IN places of refreshment a clean sparkling water-bottle is rarely the rule. The glass is usually filmy instead of bright and often presents an appearance distasteful to cleanly sentiment. It has even been suggested that there is a definite design in exhibiting on refreshment bars water-bottles not scrupulously clean, the idea being that the customer may be induced to order a bottle of mineral water instead of slaking his thirst gratuitously. Dirt is nearly always the evidence of things unseen in the shape of micro-organisms, and the public have a right to expect the water supplied to them to be in a fit condition for drinking. We go further and suggest that our health authorities might occasionally organise a system of inspection and examination of the water used for drinking purposes at railway bars, restaurants, public-houses, and other places of refreshment, and inflict a wholesome penalty on the caterer who keeps the water-bottle and the water in it in a dirty condition. It should be remembered that though, on the whole, the water-supplies in most towns are good, yet they are rarely sterile, and micro-organisms accumulate in great numbers on the deposit which sooner or later is thrown down from the water kept stagnant in a bottle. The dirty water-bottle is an offence against clean, healthy principles which require no scientific refinements to establish them. Then let scrupulously clean water in scrupulously clean containers be insisted upon everywhere.

MEDICAL EXAMINATION OF PUBLIC SCHOOL BOYS.

MUCH has been written as to the necessity for a proper medical examination of children attending public elementary schools, and there seems at last some likelihood that provision for such needs may be made by Parliament. A similar examination of the boys who enter at our large public schools may not at first sight appear so indispensable, inasmuch as they are drawn from the richer classes, and not only should they be presumably free from many disorders resulting from unwise or defective feeding, but any physical defects should be already well known to their parents who can afford constant medical supervision. The inquiry carried out by Dr. Clement Dukes, an account of which appears in another column, shows that this presumption is scarcely borne out by the facts. It is certainly surprising to find that deformities resulting from past rickets may be common among boys who enter at our public schools. Thus of 1000 boys examined, ranging chiefly between the ages of 13 and 15 years, no less than 445 presented lateral curvature of the spine and 526 had knock-knees, while pigeon-breast was observed in 126. Flat-foot, not necessarily a rickety defect, was found in 329. Dr. Dukes attributes the existence of rickets among the wealthier classes to failure of the mothers to suckle their children and to the resulting use of patent foods deficient in nourishing qualities. Another point of interest in Dr. Dukes's paper which may here be alluded to is the association of adolescent albuminuria with chilblains. Both maladies are, we believe, benefited by treatment with calcium salts and may depend on the same vascular condition. It is gratifying to find that Dr. Dukes does not attach any serious pathological importance to this form of albuminuria and deprecates any serious restrictions on a boy's pursuits on its account.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN BULGARIA.

ADDRESSING one of the sections of the recent International Congress of School Hygiene, Mrs. Watt Smyth, the author of that excellent book "Hygiene Based on Physiology for School Teachers,"[1] said that she had just returned from Bulgaria where, through the courtesy of the Government, she had been allowed to make a study of the school systems prevailing in the different parts of the country. As a result she was particularly struck by the excellence of the system of medical inspection of secondary schools, introduced by M. le Docteur Schichmanof, Minister of Public Instruction. The system has been actually in force for four years and might be copied with advantage in England. The history of Bulgaria makes this particularly interesting inasmuch as a generation has not yet passed since that country had achieved its independence. Education, Mrs. Watt Smyth said, was made compulsory in 1879 and it was significant that whereas 25 years ago of the recruits of the Bulgarian army only 10 or 12 per cent. could read or write, now 97 per cent. could both read and write, the 3 per cent. being of other nationalities. Mrs. Watt Smyth wished to make it quite clear that in all the secondary schools a medical practitioner, who in the case of girls' schools was a lady, attended every day for as many hours as was necessary. It appears from her observations that a well-equipped consulting-room is provided in each school building with all the appliances necessary for the examination of scholars. A separate health note-book is kept by the medical inspector for each child during its school life. On first admission the scholar is examined undressed and entries made of weight, height, chest measurement at rest and in full inspiration, vital co-efficient, muscular force, and physical defects. The sight and hearing are tested and the teeth examined, the general condition is considered, and the health of the parents and the diseases from which the child had suffered are entered. This examination is repeated twice a year in the upper and three or four times a year for the lower standards. If at this examination a child is found to be sickly, ill-developed, or suffering from definite disease, the parents are communicated with and the child is given leave of absence for treatment by the family medical attendant. The school medical officer visits the class-rooms and if a child is ill for more than one day he is sent home and not again admitted without a certificate signed by his family medical attendent and countersigned by the school medical officer. The latter keeps a special list of scholars suffering from any serious disorders, such as heart disease, and watched them carefully. It is interesting to note that during the past three years in the girls' secondary schools at Sofia no case of infectious disease from among the day scholars has got further than the medical officer's consulting-room and there has been no case among the boarders. The medical officer has the power

Belfast Health Commission on this point (about which they had much evidence) is awaited with great interest.

August 20th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The University of Algiers.

FOLLOWING the recent inspection of secondary schools (*écoles supérieures*) in Algiers which was made by the late M. Moissan and Professor Bouchard, who reported in favour of the founding of an Algerian university, the Governor-General of Algeria has brought the proposal before the financial delegates and they have adopted it. This vote supports the opinion of the Minister of Finance for Algeria who has urged the creation of a university for Northern Africa. M. Moissan and Professor Bouchard, in their report, had proposed the establishment of an institute of natural science, experimental botany, zoology, and hygiene, and pointed out the political and social effects of the foundation of a university which would form a powerful link between the various races which form the population of Algeria.

Elimination by the Mammary Glands.

At the Thirty-Sixth Congress of the French Association for the Advancement of Sciences, held at Rheims at the beginning of this month, M. Henri Labbé and M. Pépin communicated a paper on the above subject. Various substances absorbed by nurses can be recovered from the milk, such as garlic, onion, and asparagus, under the form of aromatic bodies. The body which most easily passes into the milk is alcohol but iodine is almost equal to it. The mammary gland seems to add to its normal function an eliminatory power for certain substances, and M. Labbé and M. Pépin considered that some products of intestinal intoxication can appear in the milk, for in the case of nurses who were ill the children whom they suckled suffered from various gastro-intestinal troubles which disappeared when the nurse was changed. M. Labbé and M. Pépin looked especially for indigo and the sulphur ethers in various milks. They laid great stress upon the chemical and biological properties of the various milks which they examined.

The Surgical Treatment of Paralytic Deformities of the Limbs.

At the same congress M. Mencière gave an account of some researches upon which he had been engaged during the last ten years as to the cure of paralytic deformities of the limbs. He showed a series of lantern slides dealing with such cases as flail shoulder-joints, forearms in forced pronation, club hands, paralytic talipes equino varus or valgus, and flail knee-joints, which gave a very accurate idea of the various deformities and of the degree of anatomical correction and of functional cure which he had obtained by such operations as musculo-tendinous grafting or other operations according to the needs of the case. Some 10 per cent. of the cases were hopeless and nothing could be done for them. 70 per cent. were curable or could be so much improved as to be practically cured, and 20 per cent. were capable of very great improvement. For example, helpless cripples were made capable of walking and those who suffered from paralysed limbs were able to give up their orthopædic apparatus and to use the limb fairly well. As to the causes of the deformities 54 per cent. of patients suffered from infantile paralysis, 15 per cent. from cerebral infantile hemiplegia, 25 per cent. from spasmodic paraplegia, and 6 per cent. from paralysis due to other causes. M. Mencière's statistics deal with 250 cases of operation.

August 20th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Anti-malarial Campaign in Italy.

THE campaign against malaria has been continued in 1906 with undiminished vigour and with considerable success. The experience of former years had proved the immense prophylactic value of quinine, and consequently increased attention has been paid during the past season to the distribution of this drug and to its effects as compared with other measures upon the salubrity of malarial districts. As will be seen by a glance at the table given below th quantity of State quinine distributed yearly has rapidly rise from 2242 kilogrammes in the financial year 1902–03, when i distribution was begun, to 20,723 kilogrammes in the prese year of 1906–07. This result has been achieved in th face of many difficulties, such as the apathy and ignoranc of the peasantry and the active opposition and competitio of certain manufacturers interested in their own speci preparations of the drug. The largest quantity *per capit* of the State quinine has been consumed in the Basilicat after which in order rank Sardinia, Puglia, Latium, Calabri the Veneto, and Sicily. It is still unfortunately the cas that the State quinine does not reach all the popul tion and that time and organisation are require to bring it freely within the reach of the poorest an most wretched in the outlying districts. Another neces sity is the State distribution of some non-bitter for of quinine for the use of children. Three years ag Professor Celli proposed for this purpose the tannate o quinine, which is insoluble, or nearly insoluble, in water an hence almost tasteless. Its introduction encountered muc opposition, however, even amongst the members of th Superior Council of Hygiene, on account of the lon accepted but mistaken belief that the insoluble salts o quinine must necessarily be inert. Experience has show on the contrary that the tannate of quinine is no les active therapeutically than the other more solubl salts of that alkaloid, while Professor Gaglio ha proved experimentally that there is a remarkable toleranc on the part of the organism towards the tannate because i is only absorbed slowly as it comes in contact with, and i decomposed by, the juices of digestion. Its toxicity is thu little or *nil*. Made up in the form of "chocolates" th tannate is readily taken by the youngest children. Amon 736 children affected with malaria in 1905–06 the tannate o quinine was used successfully by Professor Concetti in al but 19 cases (2·5 per cent.), while among 690 children treate with the tannate as a prophylactic there were only nin failures (1·15 per cent.). In all these patients it wa admirably tolerated. Its action against recidivous attack was very decided, as was likewise its antiperiodic power. From the following table it will be seen that while the consumption of State quinine has risen to over 20,000 kilogrammes the mortality from malaria throughout the whole country has diminished since 1900 by two-thirds.

Consumption of State quinine.		Mortality from malaria.	
Financial year.	Kilogrammes sold.	Year.	Total deaths.
—	—	1900	15,865
—	—	1901	12,358
1902–1903	2,242	1902	9,903
1903–1904	7,234	1903	8,513
1904–1905	14,071	1904	8,501
1905–1906	18,712	1905	7,838
1906–1907	20,723	1906	4,690

It is true that the natural tendency to variation of the mortality curve would lead us to expect a natural descent from 1887 onwards, yet it is undeniable that in 1902 a new modifying factor was introduced by the use of State quinine which has rendered this descent much more acute, and which has, moreover, greatly impeded the recrudescence of malaria since that time throughout the whole of Italy. That this improvement has not been effected by the quinine sold by private enterprise is evident from the fact that the consumption of quinine derived from this source has meanwhile remained almost stationary. It may be safely predicted that when some appropriate preparation of the drug comes to be freely used for children under three years of age the mortality from malaria will be promptly reduced to a minimum, whilst the infant mortality from enteritis will also greatly diminish. As to its preventive effects, statistics prove that the use of State quinine has been no less successful in checking the morbidity from malaria than it has been in diminishing the mortality. Thus, for example, in the Agro Romano from 1900 onwards, as the quinine prophylaxis was gradually extended, the proportion of primary infections fell from 16–17 to 0·77 per cent. and the proportion of malarious persons from 31 to 3·4 per cent. of the protected population, while the periodic recrudescence of 1905 in the different zones of the Agro Romano was not observed at all. The same end in view a disinfectant compound has been introduced into the United States Pharmacopœia, under the name liquor cresolis compositus, consisting of crude cresol dissolved in an equal weight of soap solution. The crude cresol is a variable mixture of ortho-, meta-, and para-cresols, which may be separated by taking advantage of their different boiling-points. Dr. C. N. McBryde, bacteriologist to the United States Department of Agriculture, has determined the germicidal value of this preparation for various micro-organisms, including bacillus pyocyaneus, bacillus coli communis, bacillus typhosus, and bacillus tuberculosis and staphylococcus pyogenes aureus.[1] He has found that the liquor cresolis compositus is one and a half times as active a germicide as carbolic acid, even when prepared from a cresol of low boiling-point and free from meta- and para-cresols. The germicidal efficiency of the preparation increases with the boiling-point of the cresol it contains, and solutions made from meta-cresol and para-cresol are both much stronger germicides than a solution made from a low boiling cresol, which approximates to ortho-cresol. The bulletin contains details of the experiments which were conducted for the determination of the carbolic acid equivalent. In the case of a solution prepared from a low boiling cresol a 1 in 175 dilution was superior to a 1 in 125 solution of carbolic acid in its action on bacillus coli communis. In a comparison of the action of preparations of the three cresols on the same organism it was found that in dilutions of 1 in 250 ortho-cresol was not fatal in 15 minutes, para-cresol was fatal in 12½ minutes, while meta-cresol proved fatal in seven and a half minutes. It follows that a meta-cresol is superior to para-cresol, and that both are superior to ortho-cresol. The introduction of an official preparation of the higher cresols, the germicidal value for which has once for all been determined, would be a valuable addition to medicine and surgery. Crude cresol is less poisonous than carbolic acid, it is cheaper, and, as has been shown, it has a higher germicidal value. Its solution in soap is miscible with water, turpentine, glycerine, alcohol, and fats, and is effective in dilutions of from 1 to 2 per cent. It may be prescribed in the form of a gargle, spray, douche, lotion, liniment, or ointment.

FOREIGN CONFERENCES ON EDUCATION AND HYGIENE.

THE recent successful conference in London on the hygiene of school children was the expression of an awakening of international interest in the important issues which were under discussion. Conferences dealing with some branch of the subject have recently been held in both Switzerland and Germany. In Switzerland the sixth annual conference of persons interested in the treatment of imbecile children was held this year at Solothurn. The president, in his opening address, reviewed the progress of the past decade. The number of Swiss institutions for treating imbecile children had risen in this period from 13 to 29, and the number of children treated from 411 to 1172. In 1906 the canton of Lucerne opened a public institution for the care of defective children, and this, the first case of direct public assistance, was heartily welcomed. The number of special classes—i.e., primary classes for defective children—had risen from 20 to 67 and their pupils now number 1415 instead of 567 ten years ago. The following motions were carried :—

1. Defective children—i.e., imbecile, dumb, blind, deaf, epileptic, and crippled children—should be taught in separate schools or classes in their own interest as well as that of the school and society.

2 -Experience shows that the majority of these children are sent too late, if ever to the special school.

3 To meet the defects of the Education Acts, the care of these children must be the subject of legislation, and in particular their attendance at some school must be made compulsory during the usual periods.

4. Institutions for dealing with defective children must be maintained or supported by the State.

5 An annual medical examination of children entering the primary school should be held to test their mental capacity.

6 The cost of maintenance of a child in an institution is to be charged to the canton and the parish. The parents are to be called upon to contribute in a fitting manner.

7. The Federal Council should be asked to amend the Education Acts so as to allow institutions founded by private societies to qualify for grants from the subventions given by the Federation to the primary schools, provided that these institutions accept inspection and prove to be satisfactorily conducted.

8. The cantonal Governments are likewise to be asked to support private endeavour in future legislation.

In Germany, at Mannheim, the third Congress for combating venereal disease was mainly concerned in discussing the question of teaching the laws of sex to school children. It was agreed that this proceeding was desirable, but opinions differed as to whether it was better done at home or at school. The majority were in favour of approaching the matter through simple lessons in biology. Another important branch of pediatrics will be discussed at the annual meeting of the German Society of School Hygiene, which will be held at Darmstadt; this is the care of the teeth in children. Dr. Jessen of Strassburg has drawn up a schedule of information on the matter for the consideration of school authorities. It will be remembered that the same topic produced a useful debate at the recent meeting of the British Medical Association at Exeter. It is encouraging to know that there is a universal movement to study the vital problems connected with hygiene in the upbringing of children.

THE MISTAKEN DIAGNOSIS OF TYPHOID PERFORATION.

THE *Boston Medical and Surgical Journal* of July 18th contains an important paper on the Mistaken Diagnosis of Typhoid Perforation, by Dr. C. L. Scudder. Instances of mistaken diagnosis fall naturally into three groups: (1) those in which no lesion is discoverable; (2) those in which the lesion found does not involve the peritoneum; and (3) those in which the lesion found involves the peritoneum. Among the examples of the second group recorded are cases of pneumonia, gastritis, entero-colitis, Zenker's degeneration of the abdominal muscles (beginning with hæmorrhage into the muscles), and distended bladder The symptoms of perforation—sudden abdominal pain, tenderness, rigidity, distension, vomiting, and rapid pulse—are also symptoms of peritonitis, and therefore certain cases of peritonitis due to other causes than perforation have been mistaken for the latter. Prominent among these are cases of cholecystitis and perforation of the gall-bladder. Keen has collected 34 cases in which perforation of the gall-bladder was mistaken for typhoid perforation of the intestine. In these cases seven operations were performed, of which five were complete, with one death. All of the cases in which no operation was performed were fatal. Killiani has reported a case in which there were two perforations of the intestine and a perforation of the gall-bladder in the fourth week of typhoid fever. In a case of strangulation of Meckel's diverticulum during typhoid fever an operation was performed under the diagnosis of perforation of the intestine. Another cause of mistake is rupture of infected mesenteric glands in typhoid fever. In such cases the typhoid bacillus has been found in pure culture in the peritoneal cavity. Thrombosis of the femoral and iliac veins is also a source of error. Peritonitis may occur in typhoid fever without perforation or other discoverable lesion. In some of these cases, no doubt, an impending perforation existed. Other causes of peritonitis in typhoid fever are softened splenic infarcts, abscess of the bladder wall, and abscess of the liver. Occasionally cases of appendicitis have been operated upon under the diagnosis of typhoid perforation. Dr. Scudder reports the following case. A woman, aged 38 years, was admitted into hospital on May 20th. Four weeks before she was taken

---

[1] Bulletin No. 100, Bureau of Animal Industry, United States Department of Agriculture.

Ministry of Justice but to those of the charitable institutions; they are mentally so deranged as to be classified amongst the "irresponsibles." Special heed is now paid to criminal drunkards, and the possibility of placing these individuals into State asylums, not prisons, where their habit might be broken, has been often and often discussed in medical and forensic societies. The army reports also are now made use of to show the intimate connexion between alcohol and insanity, and freedom from punishment in such cases has already been the result of the investigation, which is the more to be praised from the medical point of view, as the disciplinary power of the army authorities with us is very great.

Spondylitis Syphilitica.

A rare case of localisation of syphilitic disease in the cervical vertebræ was reported by Dr. Okuniewski in a paper addressed to the *Wiener Klinische Wochenschrift*. An officer of the navy, 25 years old, complained of pains in the neck which were at first thought to be rheumatic but which did not react at all to the usual treatment. When examined by Dr. Okuniewski the patient could not move his head and held it as stiff as possible. There was tenderness of the trapezius and sternomastoid muscles; nothing seemed wrong with the spinal processes of the vertebræ but the patient could not open his mouth sufficiently to allow an examination of the anterior aspect of the cervical vertebral column. The patellar and Achilles reflexes were exaggerated. There was mild pyrexia; the urine was normal. As the pain continued, or rather grew worse, and as the spinal processes of the third and fourth cervical vertebræ were painful on pressure and appeared a little prominent, the head of the patient was placed in a Glisson's loop and thus immobilised. As the previous history suggested a suspicion of syphilis energetic specific treatment was advised and potassium iodide with grey ointment were used. After a fortnight's continued application of these remedies a decided improvement was seen. The Glisson loop was removed and the patient simply kept quiet in bed. Later, a plaster-of-Paris collar, which made movement of the neck impossible, was applied and the patient left the hospital. After three months of careful treatment he was discharged cured. The only trace of his severe disease was a little stiffness of the neck. Neither the spinal processes nor the bodies of the vertebræ could be felt to be enlarged, and the x rays showed no departure from the normal condition. After 14 days of antisyphilitic treatment the mouth could be opened. Syphilitic lesions in the spinal column are rare, and they can be only with difficulty distinguished from the tuberculous affections; in fact the diagnosis depends on the effect of treatment.

August 14th.

Obituary.

CHARLES WILLIAMS, F.R.C.S. EDIN.

NEWS of the death of this well-known East Anglian surgeon will be received with deep regret by his many friends. He had been in his usual health until a few months ago when symptoms of malignant disease of the throat became manifest. Mr. Williams was born at Gloucester, the son of a physician of that city. After serving as a pupil at the infirmary he was elected assistant house surgeon at the Bradford Hospital. He subsequently entered Charing Cross Hospital and in 1857 took the Membership of the Royal College of Surgeons of England. In 1858 he became house surgeon to the Norfolk and Norwich Hospital, with which he was connected for nearly half a century. In 1869 he was appointed assistant surgeon and in 1878 full surgeon. He was a skilful practitioner and made a number of very valuable contributions to medical literature.

Though Mr. Williams was a very busy man in his profession he found time for antiquarian researches. One of the best pieces of work of his life is the fine collection of portraits of benefactors, officials, and physicians connected with the city of Norfolk, which now adorns the board room of the hospital. As Sir Peter Eade says in his history of the hospital, "this collection is almost entirely due to the untiring energy of Mr. Charles Williams, the senior surgeon in the hospital, who has not only by his efforts obtained the majority of them but has most kindly presented them free of cost to the governors." A short catalogue and description, extending to 81 items, was published by Mr. Williams in 1890. Among the portraits is one of the best known of Caius, who was born at Norwich. Outside the profession Mr. Williams is best known by his studies of the life of Sir Thomas Browne. He possessed a fine collection of the works of that old Norwich worthy and was instrumental in forming the Browne Library which is at present in the Norwich Castle museum, and which comes largely from the collection of the late Simon Wilkin. With Sir Peter Eade Mr. Williams was one of the chief promoters of the movement to erect a monument to Sir Thomas Browne. Among his studies may be mentioned the "Measurement of the Skull of Sir Thomas Browne," "Portraits of Sir Thomas Browne," "The Pedigree," and on the occasion of the unveiling of the Browne statue he prepared a very full "Bibliography of the Religio Medici," a second edition of which has only just been issued. His knowledge of local history and antiquities was very complete and accurate, and he made a most interesting general collection of portraits and pamphlets relating to Norfolk and Norwich worthies.

FRANCIS JAMES PEARSE, M.R.C.S. ENG., L.S.A.

THE death on August 8th of Mr. Francis James Pearse of 75, Warwick-square, S.W., at the comparatively early age of 59 years, removes from the City of Westminster a prominent local practitioner and the last male representative of an old and much respected medical family the members of which have resided in Westminster for several generations. He was the younger son of the late Mr. George Pearse of St. George's-square, S.W., with whom he was formerly in partnership and whom he subsequently succeeded. His elder brother, Mr. George Edmund Legge Pearse, F.R.C.S. Eng., who died in January, 1904, was sometime surgeon to Westminster Hospital and his uncle, the late Dr. William Grindley Pearse of Bessborough-gardens, S.W., was one of the public vaccinators recognised by the General Medical Council. Like his brother, Mr. Francis Pearse was educated at Westminster School and received his professional training at the hospital in Broad Sanctuary where he filled the post of assistant house surgeon. In 1868 he was appointed a prosector at the Royal College of Surgeons of England. He became qualified as L.S.A. in 1869 and M.R.C.S. Eng. in 1870. After he joined his father in practice Mr. Pearse was appointed surgeon to the A Division of the metropolitan police, medical officer to the United Westminster Almshouses, and for several years he was surgeon to the Western Dispensary, Westminster

The practice which he and his father carried on had been established in Westminster well over 100 years. It was founded in the reign of George III. by Dr. Grindley who had previously been an army surgeon but finally settled down in practice in Marsham-street, which was then one of the fashionable parts of Westminster. Dr. Grindley was succeeded by his son-in-law, Mr. George Pearse, who had commenced life in the navy, having been surgeon to the *San Josef*, one of Nelson's ships. On his death he was succeeded by his son, Mr. George Pearse, who died in 1891 at the age of 80 years, and was in due course, as already mentioned, succeeded by his son, the subject of the present notice.

Mr. Francis James Pearse took the keenest interest in the Volunteer movement from its early days. At the time of his death he held the post of surgeon-colonel to the Victoria and St. George's Rifle Volunteers and Army Medical Reserve. He was rather reserved in manner but those who knew him best were most warmly attached to him.

JOHN ALFRED FOX, L.R.C.P. LOND., L.R.C.P. & S. EDIN., L.F.P.S. GLASG., L.S.A.

Mr. John Alfred Fox died at his residence, Penzance, on August 6th, from nephritis, in his forty-eighth year. The deceased was the son of the late Mr. Arthur Fox of *Illogan*, Cornwall, and after being a pupil to the late Mr. J. Quiller Couch, surgeon, of Fowey, Cornwall, he proceeded to Guy's Hospital Medical School. He took his qualifications in 1890 and succeeded to the practice of the late Mr. Dodge of Penzance. Mr. Fox had an extensive practice at Penzance, he was honorary surgeon to the West Cornwall Infirmary, district medical officer and public vaccinator, and also surgeon to the workhouse; he was also surgeon to the post-office staff and education committee. He was for some years a surgeon-lieutenant in the 1st Cornwall Royal Garrison Volunteer Artillery. Mr. Fox was formerly on the Penzance borough council and actively interested himself in the establishment of a meteorological observatory for the town. He was a good sportsman and a prominent supporter of the local football and cricket clubs. Mr. Fox was very popular in

MEDICAL NOTES ON THE MAHOMEDAN PILGRIMAGE OF 1907, TAKEN FROM THE REPORTS OF THE EGYPTIAN QUARANTINE DEPARTMENT.

DURING the three months, February, March, and April, 43,271 returning pilgrims, of whom nearly one-half were Egyptians, were landed at Tor encampment to undergo quarantine as a consequence of the existence of plague at Jeddah. Of this number 3·4 per cent., or 1465, were admitted into the Tor hospitals, and of the hospital inmates no less than 29 per cent. died, showing the grave nature of their diseases. As usual on such occasions dysentery was the chief cause of illness, besides many cases called enteritis and diarrhœa. Several different varieties of dysentery were present and although in 17 fatal cases in one hospital amœbæ were only discovered during life in the evacuations of four patients the microscope revealed amœbæ in the intestinal ulcers in every case after death. In some few instances the Shiga bacillus was found and there were many instances of diphtheritic dysentery. One of the complications of the dysentery was large numbers of intestinal parasites, especially the *Ascaris lumbricoides*. Abscess of liver is rare in returning pilgrims and so is perforation of the intestine, but peritonitis, broncho-pneumonia, and albuminuria are constantly found at necropsies. The rectum and the cæcum were the parts of the large intestine most affected and even when the whole of the large intestine was infected the lesions stop abruptly at the ileo-cæcal valve. Several times the dysentery was found to be gangrenous before death. It must not be forgotten that many of the patients are very old men, worn out with fatigue, and suffering from depression after many days of great religious excitement.

Although more than 16,000 pilgrims were landed from Jeddah only two cases of plague were discovered, both towards the end of the season; both cases were fatal, one a bubonic patient who became septicæmic and then infected his wife with pneumonic plague. Many cases of malaria were seen, mostly benign tertian or malignant tertian, and occasionally the quartan variety, which yielded to intramuscular injections of quinine.

In the isolation hospital there were 123 admissions, including small-pox, chicken-pox, erysipelas, and some cases of dysentery which were admitted when the other hospitals were too full to receive them.

For the third year Dr. Gotschlich discovered cholera vibrios in a few patients who showed no clinical or pathological signs of cholera. In the surgical wards 17 cases of tropical phagædenic ulcers were admitted. The patients treated were of many nationalities—Egyptians, Turks, Russians, and a smaller number from Tripoli, Algiers, Morocco, Syria, Tunis, Bosnia, and Bulgaria.

A large number of pilgrims this year went direct from the Sudan, for the new railway now allows them to get from Khartoum to Jeddah in less than three days at the modest price of £1 per head.

At the Suakin camp 230 vaccinations were performed on the children of the pilgrims, and one healthy negress, who chose that occasion to have her first child, required, before delivery, the operation, sometimes necessary in the Sudan, of dividing the artificial hymen which is the result of sewing up the labia majora as a sequel to clitoridectomy during childhood.

The water-supply of Jeddah was well described in a recent number of THE LANCET (July 6th, p. 51), but the description of Dr. Suleiman Bey Hamada, who accompanied the caravan all the way to Mecca, makes it clear that Jeddah fully deserves the plague, though it is hard on the pilgrims coming from fairly clean countries to have to run the gauntlet there. He says that a horrible smell was noticed at a great distance from the town, and that fæcal matter and rotten fruit and vegetables were lying about everywhere. Hence arose dysentery and typhoid fever, so that every day several pilgrims died in the open street without having received any medical help. Several pious regulations exist on paper, but the local Turkish authorities have no sufficient *personnel* and are too much afraid of causing a revolt among the pilgrims to attempt to carry out the sanitary laws. During January no less than 656 deaths occurred there (including 34 from plague), mostly due to undiagnosed diseases of the digestive system. In March the deaths from plague in Jeddah reached 149, yet there is no isolation hospital and apparently no means of treating the sick! The road between Jeddah and Mecca was free from robbers this year, but more than 20 Indian corpses were left by the roadside to be disposed of by vultures and wild animals, for there is no medical man to report the death of a pilgrim on this part of the journey and still less to declare officially the cause of the death. Mecca was entered with a caravan of more than 15,000 camels and the city was found to be relatively clean, though there were many cases of dysentery and pneumonia and the small-pox patients walked about as they pleased among the throngs of excited devotees who numbered this year about 250,000. The general mortality during the feast days varied between 50 and 80 per day, chiefly amongst Indians. The pilgrims from Java and the Sudan also furnished a terrible number of deaths, but apparently there were no cases of plague transported from Jeddah.

At Yambo, on the way to Medina, the water sold to the pilgrims is said to have been disgusting, smelling badly, of a milky colour, and full of larvæ. Again, at Yambo there is no hospital provision for the sick.

Enough has been said to show the difference between the satisfactory arrangements of the International Quarantine Board of Egypt under the presidency of Dr. M. Armand Ruffer and the criminal carelessness of the Turkish Government in the Holy Places.

THE SEVENTH CONGRESS OF SCANDINAVIAN SURGEONS.

(FROM OUR OWN CORRESPONDENT.)

The Seventh Congress of Surgeons from the four Scandinavian countries (Denmark, Finland, Norway, and Sweden) was opened in Christiania on August 8th, the PRESIDENT, Dr. JERVELL of Christiania, being in the chair. The Congress was in session from August 8th to the 10th, the morning of each day being reserved for the consideration of subjects selected for discussion. During the afternoons communications were delivered by members of the Congress on various surgical topics.

On the first day Professor T. L. BORELIUS (Lund) opened a discussion on Resection of the Colon. His experience, gained from his own 29 cases, led him to the following conclusions: 1. In cases complicated by ileus primary resection is not to be performed, but a palliative operation, doing away with the ileus. 2. Where ileus is not present primary resection of the *ascending* colon may be carried out. 3. Resection of the *left* part of the colon ought not to be done as a primary operation, but one may choose between the Bloch-Mikulicz extraperitoneal operation or the operation in three stages (*séances*). 4. As to the transverse colon, a part of not too great length may be removed by primary intraperitoneal resection or by the Bloch-Mikulicz operation. If a larger part is to be removed it is best to resect the whole of the right or of the left half of the colon, according to the site of the disease, by the operations recommended above (3). 5. For the resection of the lowest part of the colon (in the vicinity of the rectum) Schlosser's operation in three stages is to be preferred.

Professor JOHN BERG (Stockholm) said that since 1890 he had performed resection of the colon in 31 cases with eight deaths. He had tried the operation in two or three stages, but felt inclined to prefer the primary resection.

Professor TSCHERNING (Copenhagen) preferred a palliative operation in serious cases, but emphasised the impossibility of laying down hard-and-fast rules for the treatment, the cases being so different.

Professor BERG read a paper on the combined method in operation for cancer of the rectum. During the years 1890 to 1907 he had operated on 156 cases of cancer of the rectum. In 48 cases a colostomy was done with a mortality of 14·6 per cent., while in 19 not severe cases amputation or resection without auxiliary incision was performed with one death. In the majority of the patients (77) amputation or resection by means of incision in the sacral region was done with seven deaths. The combined abdomino-sacral or sacro-abdominal was used only in 12 patients, of whom six died as a result of the operation. Professor Berg drew particular attention to a mishap he had experienced in four of these 12 cases—viz., gangrene of the lower stump of the rectum—and discussed the origin of this disagreeable complication and how it might be avoided.

Fellow (pathology); Mabel P. Fitzgerald, Fellow (bacteriology); Don R. Joseph, Fellow (physiology); Benjamin T. Terry, Fellow (protozoology); Bertha I. Barker, Scholar (pathology); and Thomas W. Clarke, Fellow (pathology). Grants to aid special researches have been made to the following: Robert M. Brown, New York; O. H. Bunting, Charlottesville, Va.; Katherine Collins, New York; Cyrus W. Field, New York; N. B. Foster, New York; Joel Goldthwaite, Boston; Holmes C. Jackson, Albany; Arthur I. Kendall, New York; Waldemar Koch, Chicago; W. G. MacCallum, Baltimore; Wilfred H. Manwaring, Bloomington, Ind.; J. W. D. Maury, New York; F. G. Novy, Ann Arbor; W. Ophüls, San Francisco; Richard M. Pearce, Albany; H. T. Ricketts, Chicago; Hermann W. Schulte, New York; Charles E. Simon, Baltimore; Aldred S. Warthin, Ann Arbor; and Francis C. Wood, New York.

DONATIONS AND BEQUESTS.—The Royal Westminster Ophthalmic Hospital has received a grant of £1000 from the trustees of the Zunz Bequest for the purpose of naming a ward in perpetuity the "Annie Zunz Ward."—The City of London Truss Society, 35, Finsbury-square, has received a legacy of £100 under the will of Mr. William Grain.—By the will of Mr. William Brindle £300 are bequeathed to the Devonshire Hospital and Buxton Bath Charity.—By the will of Mr. Harcourt Coates, L.R.C.P. Lond., M.R.C.S. Eng., a sum of about £20,000 is left to the Salisbury Infirmary for the building of a surgical ward to be called the "Harcourt and Maud Coates Ward."—By the will of Mrs. Duffield of Torquay, Torbay Hospital, Torquay, will receive £500.—The Rev. N. Shelmeldine has by will bequeathed £100 each to the Worcester Infirmary, the Tewkesbury Rural Hospital, the Pershore Cottage Hospital, and the Salford Royal Hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Report of the Police and Sanitary Committee.

THE Police and Sanitary Committee of the House of Commons, which deals with private Bills promoted by municipal and other authorities and proposing to create powers relating to police and sanitary regulations, has made a special report in which several matters referring to public health are touched on. The Committee states in it that the question of compulsory notification of births has been again before it and it has given the power to the Sunderland corporation. It has adhered to its policy of giving the clauses only in cases where there was a substantial voluntary effort to cope with the problem of infantile mortality. It refused them to one corporation which had no such organisation. In another case the promoters withdrew the clauses when the Committee required that the conditions should be precisely the same as those given last year as an experiment to the corporation of Huddersfield. The Committee also refers to its action with regard to "milk clauses." In the case of the London County Council Bill it considered carefully the question of amending the model clauses relating to tuberculous milk. It was satisfied as to the expediency of giving the County Council power to issue an order prohibiting the sale of milk from a particular cow or cows without necessarily condemning the whole dairy. This amendment it subsequently inserted in the Sunderland Corporation Bill. The committee also allowed power to the London County Council to defray the expenses of a dairyman appearing before it in obedience to its notice, but it allowed it only in view of the wide area from which the milk-supply of London is drawn.

The Prevention of Plague.

The recent correspondence which has passed between the Secretary of State for India, on the one hand, and the Governor-General of India in Council, on the other, on the subject of measures for the prevention of plague has been published as a Parliamentary Blue-book. It consists of three despatches. In the first despatch, which was dated Nov. 30th, 1906, Mr. MORLEY forwarded to the Governor-General a representation made by the Royal College of Physicians of London regarding plague in India and regarding the memorandum of the College submitted to the Government of India in the summer of 1905; and also a memorandum by Dr. W. J. R. SIMPSON as to the measures taken at Poona for dealing with the epidemic. The Government of India sent a long letter on May 2nd, 1907, to the Secretary of State in reply to his communication, and it inclosed a statement of views on the suggestions contained in the memorandum of the Royal College of Physicians of London on the plague. To this, on July 26th, Mr. MORLEY replied that the proposals for extending the general sanitary service by the increased employment of qualified natives, details of which he desired, would be cordially supported by him within reasonable limits of cost. The correspondence is voluminous and extends to 54 printed pages.

HOUSE OF LORDS.

THURSDAY, AUGUST 15TH.

The Vaccination Bill.

The Vaccination Bill was read a third time and passed.

HOUSE OF COMMONS.

WEDNESDAY, AUGUST 14TH.

Glycerinated Calf Lymph.

Mr. WEIR asked the President of the Local Government Board, in view of the fact that a sum of £1350 was set down on the current estimates for the hire of calves for the production of glycerinated calf lymph, would he state the number of calves hired for this sum and the average age of calves so hired?—Mr. JOHN BURNS replied: A sum of £1350 is the amount estimated to be required for the hire of calves during the current year. The number of calves hired will depend on the number found to be necessary from time to time during the year and it cannot at present be stated what that number will be. The number hired up to June 30th was 203. The average age of the calves hired last year was four months.

Mr. WEIR further asked the President of the Local Government Board, in view of the fact that during the last financial year the Board paid a sum of £860 17*s.* 6*d.* in respect of the hire of 505 calves for the production of glycerinated calf lymph, and that these calves were not on hire for more than a fortnight, whether he would explain why the Board found it necessary to pay so large a sum as 34*s.* for the use of a calf for a fortnight?—Mr. JOHN BURNS answered: Before the lymph obtained from any calf is used the calf is slaughtered and the carcass undergoes dissection and examination in order that it may be ascertained that the animal was in perfect health and free from any taint of tuberculosis. The amount paid includes the sum for the depreciation of the value of the carcass owing to the post-mortem examination. It is not found practicable to obtain suitable calves at less terms than those now paid.

THURSDAY, AUGUST 15TH.

Liverpool School of Tropical Medicine.

Colonel SEELY asked the Under Secretary of State for the Colonies whether, in view of the work already accomplished by the Liverpool School of Tropical Medicine in combating tropical diseases, he could arrange for an increased grant to be made in order that the work may be further extended.—Mr. CHURCHILL answered: A further grant will be made of which the Secretary of State will be able to specify the amount after consultation with the Treasury.

A Medical Bureau at the Board of Education.

Sir PHILIP MAGNUS asked the President of the Board of Education whether he would state what would be the constitution and personnel of the medical bureau to be attached to the Board of Education with the view to giving guidance and advice to the medical officers to be appointed by local education authorities to undertake the medical inspection of the children in public elementary schools.—Mr. MCKENNA said in reply: I am in communication with the Treasury on this matter, but I am not yet in a position to make any statement.

The Landing of Cases of Infectious Disease.

Mr. WHITEHEAD asked the President of the Board of Trade whether his attention had been called to the fact that three passengers on board the White Star liner ss. *Persic*, which sailed from Durban on March 27th, were forced to land at Plymouth, notwithstanding that they intended to proceed to Tilbury, without being informed of the risk which one of them ran from exposure to a railway journey owing to the fact that he was suffering from typhoid fever; whether the fact of this disease having occurred on board was notified to the port authority or Board of Trade; whether it ought to have been notified, and to whom; whether the summary landing of these passengers at Plymouth relieved the ship's officers from any duty of reporting the disease on arrival at Tilbury or in any way expedited the discharge of the vessel in the port of London; whether he proposed to take any action in the matter; whether his department, or other authority, had any power to prevent the spreading of disease in this way in this country; and whether, having regard to the loss and expense incurred by several persons through the above events, he would cause full inquiry to be made into the whole matter.—Mr. JOHN BURNS (in a written answer) replied: Perhaps I may be allowed to answer this question. My attention has been called to the case mentioned in it and I have made inquiry with regard to it. The passengers referred to left the ship at Plymouth under the advice of the ship's medial officer but I do not understand that they were forced to do so. The medical officer appears not to have regarded the case as one of typhoid fever but as extremely suspicious. He states that he reported the case at Plymouth to the pilot, giving him the principal symptoms as a guide for those ashore, and that the pilot assured him the case would be looked to. I am informed that the discharge of the vessel was not in any way expedited by the landing of the passengers at Plymouth. The Local Government Board has informed the steamship company that in its opinion the ship's medical officer should either have sent an intimation in writing to the port medical officer of health respecting the case or should have mentioned it on the certificate given by him with regard to the health of the passengers and crew. The Board has suggested to the company that it should be made clear to the surgeons of their ships that in all cases where suspicion exists of infectious disease on ships arriving in any port information of the facts should be sent in writing by the surgeon to the port medical officer of health. The company has given an assurance that in future this will be done.

Public Health (Regulations as to Food) Bill.

Late at night the House went into committee on the Public Health (Regulations as to Food) Bill, Mr. EMMOTT in the chair.

In the course of a discussion on an amendment moved by Mr. GRETTON

Mr. JOHN BURNS made a general statement as to the policy which the Local Government Board would pursue in administering the Bill. Regulations were to be made under the Bill and these would lie for 40 days on the Table of Parliament before they came into force. Any public body would be able to obtain copies of the rules as soon as they were made. Any apprehended hardships would be met in precisely the same way by the Local Government Board cradle admirably suited the purpose for which it was intended and we should like to see such an article a prominent feature of every elementary school in the kingdom. The carpentry of such an article might well form part of the teaching for boys, and poor people through their children might thus become acquainted with a cheap and easily made cradle which if put into practical use might lessen the appalling number of cases of overlying.

Among exhibits competing for medals was an excellent type of portable school pavilion erected in the grounds by Messrs. Christoph and Unmack (a German firm with London representatives at 31, Queen-street, E.C.). This pavilion, measuring 32 feet by 70 feet, contained two class-rooms, a physician's room, and a corridor. This type of pavilion, which has been registered under the name of the Doecker, is largely used in Germany. The exhibit, which obtained a silver medal, was equipped with hygienic school furniture made by Messrs. Mueller of Berlin. Messrs. Humphrey of Knightsbridge, London, S.W., showed illustrations of various kinds of portable iron buildings, and the Ducker Company of Kingsway, London, W.C., showed a school-house measuring 22 by 33 feet which was erected in eight days "without nail or screw." The British Challenge Glazing Company, Limited, Bank Chambers, London, W.C., showed samples of its patent flooring for hospital and general use for which it claims, among other things, that it is uncrackable, fire-resisting, and damp proof. The same firm showed a patent glazing which seems to possess genuine merits. The Plastom Asbestos Flooring Company, Bunhill-row, London, E.C., also showed a fire- and vermin-proof flooring, while the British Doloment Company, Caxton House, Westminster, exhibited samples of its patent flooring which is said to be impervious to acids and oils. The Limmer Asphalte Paving Company, 2, Moorgate-street, London, E.C., showed specimens of paving blocks and other examples of the application of asphalt. The Chaddock Mechanical Window Company, 22–25, Cornhill, Liverpool, certainly deserved the silver medal which it obtained for its exhibit. Running through the centre of the window perpendicularly is a metal rod which fits into sockets at the top and bottom of the window frame. The window thus turns about a vertical axis and can be set at any angle according to the direction of the wind, while another advantage, and not a small one, is that both sides of the window can be cleaned from the inside. The Combined Collapsible Ventilator Company, 85, Duke-street, Liverpool, also showed an improved window and a ventilator which can be adapted to existing sashes with a view to solving the problem of ventilation without draught. Ozonair, Limited, 27, Chancery-lane, London, showed the different forms of their apparatus as applied to ventilation and various manufacturing processes. Messrs. Cassels, Park-place, Stirling, N.B., who have been awarded a silver medal, showed their Clarefont wash-basin with screw-down taps, having an inner basin in which water is allowed to flow and overflow during the time of ablution in schools, a clean supply of water being thus maintained for each pupil. Experience has shown that this system is an economical one. The same firm also showed a "one each" towel distributor for providing a separate towel to each scholar without danger of its being taken away or mislaid. Messrs. Pryke and Palmer, 40, Upper Thames-street, London, E.C., exhibited a large selection of school ironmongery as supplied to the London County Council. Interesting features of their exhibit were a portable hospital bath of steel covered with porcelain enamel and a patent window fastening for asylums and other institutions whereby a window-sash can be prevented from being opened to a larger degree than an attendant may desire. The Ajax Sanitary Company, 22, Ely-place, London, W.C., exhibited their various basins and sink fittings, which have recently been described in THE LANCET, when they were shown at the annual exhibition of the British Medical Association.[1] The exhibit of the British Sanitary Company, 341, Bath-lane, Glasgow, for which they obtained a silver medal, consisted of self-acting earth closets suitable for country schools. A very large collection of urinals, closets, and latrines, several of an excellent pattern, were shown by the Leeds Fireclay Company, 2 and 3, Norfolk-street, London, W.C., and Messrs. J. Duckett and Sons, Limited, Burnley, Lancs, had a similar exhibit. For their overflow lavatories they obtained a silver medal. Messrs. John Knight and Co., 24, Gertrude-street, Chelsea, who obtained a silver medal, displayed a large selection of drainage fittings in stoneware, and the Berkefeld Filter Company, 121, Oxford-street, London, W., showed a wide range of their well-known filters. Messrs. Candy and Co., Limited, 87, Newman-street, Oxford-street, London, W., showed their excellent stoves, "The Devon Fire," which were commended in the report of the experiments carried out under the joint control of the Commissioner of Works and the Coal Smoke Abatement Society (*vide* THE LANCET, May 19th, 1906, p. 1414). The Gas Light and Coke Company, Horseferry-road, Westminster, had an interesting exhibit, as did also Messrs. Colbran and Co., 10, Mortimer-street, London, W., the "Heaped" Fire Patent, and Messrs. A. E. Podmore and Co., 32, Charles-street, Hatton-garden, London, E.C., who showed their dust-proof Bunsen burner. The Wenham Light Company, 90, Great Russell-street, London, W.C., also exhibited their new pattern inverted mantle lamps.

Furnishing and Equipment.

The two important exhibits of the Tintometer, Limited Colour Laboratories, Salisbury, and of Messrs. E. J. Arnold and Sons, Limited, Leeds and Glasgow, may be conveniently referred to under this heading. The first-mentioned firm showed apparatus and diagrams for class demonstration, together with a colour nomenclature for the precise definition of any colour. The tintometer has been applied to many purposes, industrial and scientific, and in particular has been used by Dr. George Oliver in blood examination. (Dr. Oliver's apparatus, the hæmoglobinometer and the hæmocytometer, were referred to by him in the Croonian lectures of 1896, and described in THE LANCET of Jan. 23rd, 1897, p. 251, and March 9th, 1901, p. 711.) The particular form of tintometer shown at the exhibition is adapted for educational purposes and consists of three glass standard scales in the colours red, yellow, and blue. These scales are graded into equal units, which are in colour equivalent with each other, and are used in connexion with a set of revolving colour discs, transparency frames, and diagrams. The apparatus is used not only for teaching children colours but also for testing their vision for colour blindness. Messrs. Arnold and Sons are educational publishers and also exhibited a large collection of their books and educational appliances for use in physiological and hygienic teaching, including anatomical diagrams, charts, and their well-known "Food Values Diagrams." The chief feature of their stall was, however, "The Spectrum Colour Scheme," which has been worked out by Mrs. Florence Kirk, M.R.San.I., the head-mistress of the Belle Vue Council School, Bradford. This scheme embraces a system of teaching in which improved kindergarten methods are used in conjunction with systematic instruction in the recognition of the prismatic colours. In connexion with this scheme the firm supplies an excellent prism at a low price, and paper, wool, paints, crayons, and chalks of a practically uniform standard of colour. It is worthy of note that the instruction has been so graded that no undue strain is put upon the eyes of young children. The Educational Supply Association, 42, Holborn Viaduct, London, E.C., among other educational appliances, showed some excellent adjustable desks, notably the "Farringdon," which is so designed that both desk and seat can be adjusted to suit pupils of any height. This is an important consideration when the ages of pupils vary to any great extent. The adjustable desks and laboratory fittings of the Bennett Furnishing Company, 47, Glengall-road, Peckham, London, S.E., also deserve notice. Messrs. Thomas J. Syer and Co., of 45, Wilson-street, Finsbury, London, E.C., had a very interesting collection of fittings and tools for technical schools and laboratories. Particularly noteworthy was their exhibit of metal-working tools and bench in connexion with "hand and eye training." Messrs. Harbutt, Bathampton, Bath, makers of the well-known plastic paste, "Plasticine," had an interesting exhibit of this substance, which has many uses beside modelling, such as the making of temporary cells for microscopic purposes, and so forth. Messrs. Merritt and Co., 8, White-street, Moorfields, London, E.C., exhibited their steel lockers for use in schools, and the "England Works," of Leeds, their excellent cloak-room fittings. Messrs. Newton and Co., 3, Fleet-street, London, E.C., showed their optical lanterns, and Messrs. Fletcher, Russell, and Co. a selection of their well-known furnaces, blow-pipes, and various laboratory appliances. Messrs. Spencer, Heath, and George, Limited, Goswell-road, London, E.C., showed a completely

Manual of the Diseases of the Eye. For Students and General Practitioners. By Charles H. May, M.D., Chief of Clinic and Instructor in Ophthalmology, College of Physicians and Surgeons, Medical Department, Columbia University, New York, 1890-1903. Fifth edition, revised. Price $2.00 net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Archibald, John W., M.B., Ch.B., has been appointed on the Resident Medical Staff of the Royal Infirmary, Aberdeen.

Ball, W. Girling, F.R.C.S. Eng., has been appointed Assistant Surgeon to the City of London Truss Society.

Gask, G. E., F.R.C.S. Eng., has been appointed Surgeon to the City of London Truss Society.

Gorham, P. C., L.R.C.P. & S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Clifden District of the County of Galway.

Harvey, Frank, M.R.C.S., L.S.A., has been appointed Public Vaccinator for the St. Issey and St. Breock Districts by the St. Columb (Cornwall) Board of Guardians.

Hustler, G. H., M.B., Ch.B. Leeds, has been appointed Government Medical Officer for Fiji.

Niven, A. M., M.B., Ch.B., has been appointed on the Resident Medical Staff of the Royal Infirmary, Aberdeen.

Stewart, Alex., M.B., Ch.B., has been appointed on the Resident Medical Staff of the Royal Infirmary, Aberdeen.

Walford, Harold R. S., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon at the Coventry and Warwickshire Hospital, Coventry.

Wilkins, Eric M., M.D. Vict., M.R.C.S., has been appointed Assistant Medical Officer to the Metropolitan Asylums Board.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bedford County Hospital.—House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

Bombay Municipality.—Two Assistant Health Officers. Salaries Rs. 750, rising to Rs. 1000, and Rs. 600, rising to Rs. 750 per mensem respectively.

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary £100 per annum, with board and lodgings.

Bury Infirmary.—Junior House Surgeon. Salary £80, increasing to £90, with board, residence, and attendance.

Cairo, School of Medicine (Egyptian Government, Ministry of Education).—Assistant to the Professor of Pathology. Salary £E. 320 per annum.

Cancer Hospital, Fulham-road, S.W.—Two Assistant Anæsthetists. Honorarium of 25 guineas each.

Carlisle, Cumberland Infirmary.—Resident Medical Officer. Salary at rate of £80 and £100 per annum, with board, lodging, and washing.

Derby County Asylum, Mickleover.—Junior Assistant Medical Officer. Salary £120, rising to £150 per annum, with apartments, board, washing, and attendance.

Dudley, Guest Hospital.—Assistant House Surgeon for six months. Salary £60 per annum, with residence, board, and washing.

Dumfries and Galloway Royal Infirmary.—Assistant House Surgeon. Salary £40 per annum, with board and washing.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer to the Casualty Department, also Second Medical Officer, both for six months, renewable. Salary of former at rate of £100 and of latter at rate of £40 per annum, with luncheon and tea. Also House Surgeon for six months. Salary £25, with board, residence, laundry, &c.

Edmonton Workhouse, Upper Edmonton.—Assistant Medical Officer. Salary £180 per annum, and residential allowances.

Egyptian Government, Kasr-el-Ainy Hospital.—Resident Medical Officer. Pay £250 a year, with quarters, servants, washing, coals, and light.

Epsom, Surrey, London County Asylum, Long Grove.—Fourth Assistant Medical Officer. Salary £180 a [illegible] board, apartments, and washing.

of satisfaction to Londoners to learn that the London County Council has within the last few days practically obtained powers similar to those comprised in what are sometimes spoken of as the "Manchester Milk Clauses." As regards the causation of infantile diarrhœa and kindred ailments Dr. Hope has found as the result of investigations carried on over several years that amongst infants under three months of age either wholly or partially fed during the summer on artificial foods the deaths are 15 times as great as amongst an equal number of children fed upon breast milk, and although this proportion diminishes as the months of the first year of life advance the death-rate amongst those fed upon artificial foods are always much higher than upon those suckled by the mother. The municipal milk depôt continues to give satisfaction, but we are glad to see that its employment is regarded as a *pis aller*, the milk being intended solely for such infants as cannot be suckled by their mothers. As Dr. Hope states, there must be no misunderstanding upon this point, and the mother's milk must always be insisted upon where maternal suckling is practicable. The facts as regards the depôt are thus presented: "Out of 7520 infants coming very promiscuously to the depôts at varied ages and in conditions of health below the average the mortality was 96 per 1000 as against 171 per 1000 for the whole city, and 110 to 113 for the best districts, and 231 to 246 for the worst." We assume that the 7520 infants were all below one year of age. With respect to the subject of school hygiene it is satisfactory to learn that Dr. Hope has succeeded in obtaining the appointment of an additional assistant medical officer of health, who will, we gather, devote himself largely to this branch of public health.

County Borough of Stockport.—Dr. Meredith Young, in urging the town council of the borough to undertake a system of medical inspection of the school children in the local schools, refers to the experience of New York as regards the enormous percentage of defective children. Of 99,240 children examined in the borough of Manhattan from March 27th, 1902, to Sept. 29th, 1906, as many as 65,741, or some 65 per cent., were said to be in need of medical treatment. Some 30 per cent. manifested vision defects and 39,778 needed attention to their teeth. As many as 38,273 children are stated to have had swollen glands in the neck as the result of some present or past trouble in the throat, nose, ear, or some abnormal constitutional condition. Enlarged tonsils were found in 18,131 children, while 10 per cent. had adenoids. Heart disease was present in 1659 children and lung disease in 1039. This is a remarkable record and possibly the standard adopted in certain particulars was somewhat high, but Dr. Meredith Young will, we trust, succeed in securing medical inspection of the Stockport children.

County Borough of Oldham.—At the beginning of 1906 the Oldham town council adopted the voluntary notification of pulmonary tuberculosis for a trial period of six months, but we doubt whether this is long enough to enable any useful experience to be gained as to the utility of the measure. Doubtless some of the practitioners will wish to see in what way the officials of the health department deal with the information received; whether, for instance, it is used to help the patients or whether to place restrictions upon them which will render it difficult for them to obtain a livelihood and so, by lowering the resistance of the remainder of the family, encourage the development of an already latent infection or of a fresh infection. A longer limit than six months should in any case be fixed. We are glad, however, to note that in the absence of notification the disease, as measured by the death-rate, is undergoing a steady fall in Oldham.

County Borough of St. Helens.—Dr. J. J. Buchan states in his current annual report that use is now being made of an empty pavilion at the isolation hospital for the education of cases of pulmonary tuberculosis much on the same lines as the practices adopted at Manchester, Brighton, and other places. During 1906 42 patients were admitted, and of these 34 were discharged improved. The remaining eight died. The average duration of stay was 41 days. Voluntary notification of this disease has been in operation in St. Helens since 1899, and, on the whole, the medical officer of health is well pleased with the results.

County Borough of Derby.—Voluntary notification of pulmonary tuberculosis has been in operation in Derby since 1902, and Dr. M. J. Howarth reports that all cases are being notified which in the opinion of the attending physician should be visited by the health officers. In addition to the usual instructions based upon the belief that the chief cause of the disease is infection from person to person the sanitary condition of all the invaded houses is gone into, more especially as regards the presence or absence of thorough ventilation.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8578 births and 3625 deaths were registered during the week ending August 17th. The annual rate of mortality, which had been equal to 11·9, 11·7, and 11·8 per 1000 in the three preceding weeks, was again 11·8 in the week under notice. During the first seven weeks of the current quarter the death-rate in these towns has averaged 12·1 per 1000, the rate in London during the same period being 11·9 per 1000. The lowest death-rates in the 76 towns last week were 4·1 in Croydon, 4·2 in Willesden, 5·6 in Hornsey, and 5·9 in Devonport; the highest rates were 17·1 in Bolton, 17·2 in Birkenhead, 17·7 in Great Yarmouth, 17·8 in Merthyr Tydfil, and 18·7 in Stockton-on-Tees. The 3625 deaths in the 76 towns showed a slight decline from the number in the preceding week and included 407 which were referred to the principal epidemic diseases, against 362 and 378 in the two preceding weeks; of these, 130 resulted from diarrhœa, 102 from measles, 92 from whooping-cough, 38 from diphtheria, 23 from scarlet fever, and 22 from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered last week in Croydon, Tottenham, Leyton, Middlesbrough, Stockport, or in 14 other of the 76 towns; the annual rate from these diseases, however, ranged upwards to 3·9 in Bootle and Stockton-on-Tees, 4·9 in Walsall, and in 6·1 in Cardiff. The deaths from diarrhœa, which had risen from 39 to 104 in the five preceding weeks, further increased last week to 130, the death-rates from this disease ranging upwards to 1·3 in Sheffield, 1·5 in Warrington, 1·6 in Wallasey, 1·7 in Rotherham, and 3·1 in Bootle. The fatal cases of measles, which had declined from 142 to 94 in the four preceding weeks, rose again last week to 102; the death-rate from this diseases was 1·4 in Merthyr Tydfil, 1·5 in Blackburn, 1·7 in Derby, 3·0 in Stockton-on-Tees, 3·8 in Walsall, and 4·2 in Cardiff. The deaths from whooping-cough, which had been 86 and 85 in the two preceding weeks, rose again last week to 92, and caused death-rates ranging upwards to 1·1 in Newcastle-on-Tyne and 1·2 in Walthamstow. The 38 fatal cases of diphtheria showed a slight decline from the number in the previous week; the highest death-rate last week from this disease was 1·5 in Warrington. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday, the 17th inst., was 3669, against numbers increasing from 2658 to 3680 on the 14 preceding Saturdays; 430 new cases were admitted during the week, against 557, 419, and 466 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 136, 137, and 139 in the three preceding weeks, declined to 129 last week, but were slightly in excess of the corrected average number in the corresponding period of the five years 1902–06. Three deaths were attributed to cerebro-spinal fever in London last week, against one in the previous week. The causes of 38, or 1·0 per cent., of the deaths in the 76 towns' last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Leicester, and in 47 other of the 76 towns; three uncertified deaths were registered in Manchester, three in Rochdale, and two each in London, Liverpool, Birmingham, Sheffield, Preston, South Shields, Burnley, Northampton, Merthyr Tydfil, King's Norton, and Hanley.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 12·8 and 13·8 per 1000 in the two preceding weeks, declined again to 12·6 per 1000 in the week ending August 17th, but exceeded by 0·8 per 1000, the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 8·7 in Leith and 11·6 in Edinburgh, to 14·7 board of management consisting of five deputy governors was constituted. In 1889, as the result of a commission appointed to inquire into the manner in which the hospital was managed, an Ordinance was passed making the hospital a Government institution to be appointed by the Governor and under rules and regulations to be approved by the Governor. This Ordinance, slightly amended, is still in operation. The board of commissioners consists of a chairman (the colonial secretary) and five others, of whom not less than three, including the chairman, must be civil officers of the colony. A surgeon, an assistant surgeon, and a dispenser reside in the hospital. There are also a resident matron and five nursing sisters, obtained through the medium of the Colonial Nursing Association in England. An additional block was erected in 1904 at a cost of £3691. This enabled the Government to provide a new "home" with improved accommodation for matron and sisters and separate wards for female lock cases. A public dispensary is maintained at the hospital, at which persons certified to be indigent receive medical advice and medicine gratis. Persons certified to be in straitened circumstances are given medical advice and medicine on payment of a small fee. At one time the Spanish Government made an annual grant of 1250 pesetas towards the funds of the hospital, in consideration of which Spanish subjects resident in the neighbouring town of Linea received gratuitous medical treatment on the production of certificates of indigency signed by the Alcalde (Mayor) of that town. In 1891, shortly after the hospital became a Government institution, this grant was discontinued at the request of the Gibraltar Government. The practice of affording gratuitous medical treatment to residents of Linea, however, still obtains. A small building, with accommodation for two beds, was erected in 1884 at an isolated spot on the North Front. It was intended for the receipt of small-pox cases landed from ships and was considered to be a branch of the civil hospital. Two wards of four beds each were added in 1889. Until 1893 small-pox cases occurring in the town were treated in the segregation wards of the civil hospital. In that year it was decided that they should be received into the branch hospital at the North Front, but no additional accommodation was provided. During the epidemic of 1896 temporary provision was made for eight or ten more beds by the erection of a wooden building. The naval and military authorities have recently added two buildings with eight beds each for the reception of military and naval cases. The Colonial Government contemplates making additions and improvements to its buildings at an early date. The hospital is in charge of an assistant surgeon, subject to the general supervision of the surgeon of the Colonial Hospital. The number of patients under treatment at the Colonial Hospital in 1906 was 632 (495 males and 137 females). Of these 423 were discharged as cured, 84 as relieved, and 28 as not improved. There were 46 deaths. In the small-pox hospital there were 122 under treatment during the year (82 males and 40 females). Of these 99 were discharged cured and 11 died. The average stay of those who were discharged cured was about 42 days. The number of persons seeking treatment at the Colonial Hospital as out-patients continues to increase, no less than 12,367 persons (of whom 982 came from Linea) having been treated in 1906, as against a total of 10,584 in 1905 and 6397 in 1904. New buildings were erected in 1884 for the special purposes of a lunatic asylum, which was placed under the direction and management of the police magistrate, subject to the control of the Governor. There is a resident superintendent and the surgeon of the Colonial Hospital makes daily visits. Patients are admitted on the order of the police magistrate and certificate of any two duly qualified medical practitioners. There were 46 patients under treatment during last year.

BIER'S TREATMENT.

To the Editors of THE LANCET.

SIRS,—Will some kind reader please tell me where I can find a detailed account of Bier's treatment?

I am, Sirs, yours faithfully,

MAC.

August 17th, 1907.

POPULAR BACTERIOLOGY.

WE fear that the Paris correspondent of the *Daily Telegraph* has been the victim of a "scientific" hoax; if not, he must have seriously misunderstood the information which was given him about the bacteriological flora found in a first-class carriage on the Bordeaux "rapide" train. He summarised the result of this inquiry in a recent issue of the *Daily Telegraph* and described the germs found in the carriage as follows: (1) penicilium (*sic*) glaucum, which produces appendicitis; (2) Asperbillus (*sic*) niger, which affects the digestion; (3) Bacterium Termo, or Proteus zuckeri, which generally weakens the human body (this seems a mild way of putting it); (4) stapylococcus (*sic*) pyogenes aureus, which begets phlegmon; (5) Micrococcus tetragenos of tuberculosis; (6) Koch's bacillus of tuberculosis; (7) Klebsloffler's (*sic*) bacillus of diphtheria; (8) the coli bacillus which produces typhoid; (9) streptococcus lanceolatus niger, the microbe of pneumonia; and (10) Legros' bacillus septicus, which inflicts gangrene. Thus "bad begins but worse remains behind," for the playful comment is appended, "Dr. Legros' charmingly named 'sceptical bacillus' may finish you off. The sceptical microbe gives you gangrene, an affection of which there is no possible doubt." If the contributor to our esteemed contemporary had been inoculated with the "sceptic" microbe he might have avoided making the above errors.

THE SEVEN STAGES OF DRINK.

AN interesting medical pendant to Shakespeare's great picture of the seven ages of man was furnished by a medical man when giving evidence at Marylebone police court recently. The practitioner, as reported in the daily press, took for his text not mankind in general but the drunken individual, and described seven stages in his evolution. He began by stating that he had found the defendant in "a mellow, comfortable state of drunkenness and recovering from irritation." This analytical description led Mr. Plowden, the officiating magistrate, to inquire further into the normal course of drunkenness and he drew from the witness the following list of the successive stages of an attack of alcoholic intoxication: 1, irritable; 2, mellow and comfortable; 3, pugnacious; 4, affectionate; 5, crying; 6, collapsed and incapable. But even this did not satisfy Mr. Plowden and he induced the witness to add his seventh stage as a finishing touch: "If you give them a little more—death." The magistrate was very interested and expressed a hope that the defendant would profit by the professional instruction she had heard. The medical man certainly produced a very complete composite clinical picture, but all the cases of drunkenness do not, of course, pass through the first six stages; the average drunkard exhibits one or two of them to the exclusion of the others, as no doubt the witness would have said had he been asked.

THE VALUE OF BLOOD SERUM IN SURGERY.

IN connexion with an article on the Use of Animal Blood Serum in Surgery, by Mr. W. Stuart-Low, which was published in THE LANCET of May 4th, 1907, p. 1221, our attention has been drawn to a statement that bovinine, which is a defibrinated *bullock's* blood carefully preserved and containing all the elements of nutrition present in arterial blood, has been employed by many surgeons throughout the United States as a topical dressing in granulating surfaces and chronic ulcerations as well as in general tissue necroses. It is claimed that while serum albumin is of undoubted value yet its field of usefulness as compared with bovinine is narrow. While bovinine is sterile it is said that it not only protects the newly forming granulations but to some extent also supplies nutritive agents which encourage the healing process. Bovinine is simply applied to the surface of the wound or skin-graft, the sterile gauze being retained in position by a sterile gauze bandage kept constantly wet with bovinine. This plan prevents the dressing from becoming irritating and offensive which is often the case when it is protected by oiled muslin or a silk or rubber tissue.

◆

Provincial.—D was right in going to the case in the circumstances and evidently he is ready to hand over the case to E. If, however, the patient insists that D continue in attendance she has a right to do so.

Interested.—Our correspondent must not advertise his invention as Dr. ——'s patent tooth brush.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

THE NEW ADVANCE AT THE INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

To the Editors of THE LANCET.

SIRS,—As a slightly incorrect statement was published it would be as well to explain in some detail the important new move in the matter of school hygiene which was taken at the closing meeting of the recent International Congress.

The permanent international committee, consisting of about 60 members selected from almost every country, has hitherto only met during congresses. Arising out of the question of whether it would not be a proper thing to establish a bureau, with a permanent staff, library and museum, and so on, in some central but neutral spot, such as a Swiss or Dutch town, it was decided, as explained by Dr. Mathieu, Dr. Burgerstein, and Dr. Kerr, that it would probably lead to greater progress if such bureau was not localised, but if each country had its own centre for the diffusion of knowledge and to act as a clearing house in the matter of school hygiene statistics, laws, and regulations. Finally, to supervise in scientific matters and generally to do all that is possible at all times or places to forward the human interests which are bound up in the special lines of knowledge included in school hygiene the international committee has formed a small council.

This council has all the powers of an ordinary committee. It can form subcommittees of experts on special inquiries. The usual committee procedure is to sit round a table and discuss matters, but this council will deal with the various subjects that arise, submitting the different topics by correspondence, collating the answers, and finally making pronouncements in urgent matters after a meeting of the council.

It is obvious that for efficiency such council should be small and yet have in it elements to secure permanence and at the same time possibilities of slow but constant change. This has been done by deciding that it shall consist of the president of the past congress, the president of the congress which has just been held, and the president of the next congress. Nine other members are to be elected, of whom three are to be from the country where the congress was last held and three from the country where it will be held next, three being selected from other lands.

Certain matters, for instance, will almost at once come under the consideration of this council. Such might be quoted as:—

The question of how medical inspection of schools can best be carried out with the maximum of efficiency and minimum of cost.

The question of how far the laws of health can best be imparted to the coming generation so that later they will know how to care for themselves and those dependent on them.

The best systems or methods of physical training for both sexes at various ages.

The feeding of children requiring proper nutrition, so that it shall be done without developing pauperism and with regard to those upon whom the cost falls.

These four matters are being dealt with practically in a great variety of ways, and this council should be able to collect and analyse known facts to show which methods are best for any town or State.

It is obvious that information thus digested will have a very great value politically as well as educationally, and this council may in time come to be officially regarded as quite analogous in matters of school hygiene to that other congress of peace now in session at the Hague.

Yours faithfully,

LAUDER BRUNTON,
President of the Second International Congress on School Hygiene.
JAMES KERR,
E. WHITE WALLIS,
Honorary General Secretaries.

SOME PHYSIOLOGICAL EFFECTS OF HIGH-FREQUENCY CURRENTS IN DISEASE.

To the Editors of THE LANCET.

SIRS,—Dr. J. C. Bowie, in his letter in your issue of August 3rd, p. 318, seems to desire to draw me into a discussion on the nature and methods of measurement of high-frequency currents rather than to make an attempt to criticise my records of the physiological effects of these currents in disease. He propounds some electrical problems which would be interesting if anyone were able to solve them, but which are apt to draw the attention of your readers away from the subject which I wished in my paper to direct their attention to. The problem he asks me to solve, regarding the wattage I am able to obtain, is a puzzle to me as well as to him. The only possible answer meantime is, I suspect, that the term wattage can hardly, with our present knowledge, be applied to high-frequency, so-called, currents. His statements as to the action of these currents on the human body are evidently based on his experience of the ordinary relatively low-tension currents. When we come to speak of high potential and high-frequency currents, however, I think the time has passed for anyone to say what might not be safely applied to the body. Professor D'Arsonval, indeed, is said to have passed a current of three ampères into his body in circumstances where the potential must have been terrific, and with, it is said, no inconvenience. Whilst I should not perhaps have the courage to do this, what right have I to say that I do not believe it to be possible?

It is granted by physicists and is a matter of daily observation that the potential of these currents is enormous; but if Dr. Bowie is familiar with this mode of treatment he should know that when a "current" of 500 milliampères is spoken of it is not meant that anyone can say exactly what this actually means, only that it is the heat equivalent of an ordinary galvanic current of this amount, and that to this extent it corresponds to a current of that amount. If Dr. Bowie can say exactly what it does mean more fully most of us, electricians and electro-therapeutists, will be grateful to him; but this, though most interesting, has little to do with the matter at present in hand. When we speak of 500 milliampères as registered by the thermic milliampèremeter we speak in terms quite intelligible to all workers in this field, since we speak of a standard by which may be tested the validity of my records, because we are using the same instrument and speaking the same language. But, although I have generally, if not always, indicated the amount of current as thus measured which I was employing during my experiments, I have, by intention, avoided going into the question of the different physiological action of differing doses, leaving this and many other points for future study by myself and by others as I have before stated. My investigations since the publication of my paper in THE LANCET are more in the direction of the therapeutic possibilities of varying degrees of frequency of these currents. This also may prove a fruitful field of inquiry.

Dr. Bowie complains of my failing to take note of the importance of voltage in my records. If he refers to No. 1 of the "Questions worthy of consideration as to future investigations," he will see that he has made a mistake here. I know of no previous experiments in this direction. I am uncertain even if anyone had considered this question to any practical extent before I referred to it myself, and so I am at a loss to know why he should think that I inquired to be informed as to the importance of voltage when investigating the physiological effects of these currents in disease. Let me repeat that my object in my paper was to prove mainly that high-frequency currents had a varying effect in disease, not an invariable one, as in health; nay, more, an effect not only differing according to the nature of the disease but differing with the varying condition and environment—mental and physical—of the patient at the time of administration. This is surely sufficiently important and sufficiently in advance of previous researches to make it worthy of criticism without spending time upon first trying to solve some electrical problems associated with high-frequency currents.

Dr. Bowie says that the consideration of five factors is greater than in most other callings, and the risk of leisure for which reasonable occupation is hard to find need never be present to one who is entering upon the study of medicine. It is particularly in the second half of the hospital curriculum, when the student enters upon his strictly technical work, that he finds himself better placed than his contemporaries in other walks of life for unconsciously practising the higher virtues. Heaven forbid that we should schedule these virtues or that a progressive university should include their exercise amongst the compulsory subjects in an overloaded curriculum. It has been assumed by some hysterical writers that the frequent contact with pain and suffering which is a necessary feature of hospital life induces in medical students, and therefore in medical men, hardness of heart and want of sympathy. That such contact enables medical men to perform their necessary professional service without the exhibition of emotion is, of course, true, but that this implies the development of inhumanity is false. The constant opportunity of social service that a medical student can find in the wards and out-patient departments of our great hospitals is the best possible means of training his character for his future work. There is, perhaps, room for development in our hospitals of coöperation with other agencies, medical and lay, engaged in dealing with social problems. The meaning of, and the possible remedy for, the life tragedies revealed in our hospital wards would thus be made clearer. There is too much tendency, in London, at any rate, for each hospital to regard itself as an independent factor in dealing with disease. In the solution of the many sociological problems that confront us the medical profession is destined to take an important part, and there could be no better preparation for a medical man to carry out his share of the work than in studying fully the social conditions of the patients that apply for treatment at the hospitals. But the training would be still more effective if the student were taught something of the way in which sanitary, poor-law, and other authorities coöperate with the hospitals and the medical profession in the prevention as well as in the treatment of poverty, crime, and disease.

The Limitations of the Medical Curriculum.

From the intellectual and more strictly educational standpoint the curriculum imposed upon medical students by the universities and licensing corporations has many defects. The curriculum is overcrowded, it is far too rigid, and above all it is seriously hampered by the requirements of the examinational system. The medical student may as well know these things on the threshold of his career. The mere school-boy must accept without question the course of study laid down by his masters; no good comes from raising doubts in his immature mind as to the advantages of the modern methods of education. But just as liberty to work or play must gradually be given to the undergraduate, so may the medical student, sometimes already a graduate, be invited to criticise the plans suggested for his education, and he should be allowed to some extent to choose for himself the methods best suited to his particular circumstances. Of course, he must pass his examinations, for only by passing examinations can he satisfy the State that he is fit to practise medicine. But we would strongly urge all students now commencing their studies to peruse the regulations put into their hands authority not as if they were *inspired* documents to literally obeyed but in a spirit of intelligent critici Let these regulations be recognised as attempts, no means altogether successful, to meet the requir ments of the average man and to checkmate the idle while holding the balance fairly as between the opposin interests of universities, medical corporations and school and the State, and between the conflicting claims the advancement of the science of medicine and th practical application of our art to the healing of disease Properly regarded in this light as a compromise betwee many divergent views it is clear that official regulations ca indicate an ideal course for very few individuals. Som men learn best from systematic lectures, others fron personal intercourse with a demonstrator, others again from practical laboratory work, and still others by the burning of midnight oil over the perusal of text-books or monographs. An official curriculum must provide for all these methods of instruction, but the student himself and his most intimate teacher can say alone in what proportion they should be combined in any individual case. It is only after careful perusal of the regulations and conferences with a trusted teacher that a student can learn how far he may risk a relaxation of regulations in one or other direction in order that he may pursue to the full the course of study which will best develop the powers of his mind.

It is first essential that a medical student should have clearly before him the fact that the sole object of his five years' course of study is not the passing of his examinations. The passing of examinations is an incidental necessity of medical education, but the success of any man's course of study may be measured by the extent to which he has been able to shake off the fetters of the examination system. Harmful as is this system to true education, a great deal of its disadvantage could be avoided by a candid recognition by the student of the truly incidental character of an examination. He who reads a book or attends a course of lectures or practical work with the object of answering the questions which arise or have arisen in his own mind is making a proper use of the book or of the course of instruction. The moment he consciously uses either book or lecture in order to prepare himself to answer other people's questions the spirit of cram has entered and the spirit of true education suffers. To many students it may seem that this differentiation between the proper and the improper attitude towards their work is a subtle one and hardly to be maintained. It is just because it is so subtle that there is danger of its being overlooked. It is, however, vital, and the student who *learns* biology or chemistry not because he wants to *know* the deeply interesting facts of these enchanting sciences but because he wants to be able to answer the questions which the examiners at the preliminary scientific examination will ask a few months later, starts his medical education in a wrong spirit and bids fair to become one of the unhappy slaves of the examination system. Fortunately, there is no excuse, so far as the subjects of medical examinations themselves are concerned, for approaching them in any spirit but that of the

the temperature was again 100°, and as the bowels had still not been opened I ordered a little carbonate of magnesia. On the 9th I saw her again, when the temperature had risen to 101° again, and as the bowels were still confined I ordered grain doses of hydrargyrum cum creta. On the 10th the temperature rose to 102°. I began to suspect typhoid fever and treated her on those lines. I ordered an enema and the day after—viz., August 11th—the child had a good opening and the temperature fell to normal. I examined the stools and although they looked somewhat pea-soupy in colour they were certainly not distinctive and not very offensive.

Although the temperature fell to normal and the child seemed much better I again made a very careful examination, still bearing in mind a possibility of typhoid fever (on account of the stools and the somewhat apathetic appearance of the child), but could not find any trace of that disease. The spleen was not palpable nor was its percussion area enlarged, and there was no tenderness in that region The tongue was certainly not characteristic and the pulse was not dicrotic. There were no rose spots to be seen; although it being only the sixth day of illness it was perhaps still somewhat too early to expect them. There was slight congestion of the lungs and I therefore suspected a hidden pneumonia or acute miliary tuberculosis, although the breathing was not of the pneumonic type and there were no other symptoms or signs to suggest any lung mischief. The child complained of some headache, but there were no other signs whatsoever of any cerebral or meningeal trouble. There was no squint, no retraction of the head, no Kernig's sign, and an ophthalmoscopic examination gave an entirely negative result. The ears and nose were examined, but absolutely nothing abnormal could be discovered. The apathetic appearance and somewhat drowsy condition of the child began to worry me a little, and therefore, when I found on the next day, the 12th, that the temperature had again risen to 102°, I called into consultation Dr. Cecil Wall. In spite of the most careful, prolonged, and very searching examination no definite conclusion could be arrived at, all signs being absolutely negative, although this was already the seventh day of the illness. It was decided to watch the case till the tenth day and that I should then examine the blood for Widal's reaction. The consultation was held at 1 P.M. and at 4 P.M. I saw the little patient again, when her face was extremely flushed, her lips were tremulous, and she was plucking at the bed-clothes. The temperature was then 106·4°. I immediately telephoned to the consultant to come to see the child again, but before he arrived the patient died from collapse. No post-mortem examination was made.

The case presents two points of interest. Firstly, What could have been its nature? Secondly, assuming even that it was typhoid fever why should the child have died so suddenly from hyperpyrexia and collapse when only a few hours ago there appeared to be every prospect of a good recovery?

I am, Sirs, yours faithfully,
M. FELDMAN.
London, E., August 16th, 1907.

AN ASSOCIATION OF SHIP SURGEONS.

To the Editors of THE LANCET.

SIRS,—In answer to many letters which I received concerning my letter in your issue of August 17th may I be allowed further space to say on behalf of the B.S.S.A. (British Ship Surgeons Association) which is being formed that its aims are:—Firstly, to improve the "status" of ship surgeons. Secondly, to issue a ship surgeons' gazette monthly, in which will be published "dissertations" on diseases peculiar to sea-going persons. Members will be expressly invited to narrate their experiences and views concerning the treatment of such affections as sea-sickness, &c. A special article on "Marine Hygiene" will appear in each issue. Thirdly, to provide a medium for advertisement of "vacant posts" and "posts wanted."

The way in which it is proposed to improve the "status" of medical officers will be discussed at length later, when it is hoped that members will forward suggestions on the proposition in question. That there is need for this movement there can be very little doubt, judging from the "pay" of ships' medical officers, which does not compare favourably with that of surgeons holding equally responsible positions ashore. A committee will be formed of 12 past and present ship surgeons, six "past" and six "present." The six senior surgeons of the leading shipping companies in Great Britain will be asked to stand as the six present members.

The joint positions of honorary secretary and treasurer will be filled *pro tem.* by myself until it is convenient for the committee to fill the "posts." The annual subscription (to include monthly gazette) is proposed to be 10*s.* 6*d.* per member, which, however, is not to be forwarded until further notice. It is hoped that all medical men eligible for membership will come forward and render all the assistance possible in the formation of this much needed association. Applications for membership and other communications will be gratefully received by

Yours faithfully,
G. METCALFE-SHARPE,
Late Surgeon P. and O. and Cunard Steamship Companies.
Angram Hospital, Middlesmoor, Leeds, August 19th, 1907.

THE TREATMENT OF TUBERCULOSIS AND LEPROSY.

To the Editors of THE LANCET.

SIRS,—In a preliminary note on the Successful Treatment of Tuberculosis and Leprosy (published in THE LANCET of April 13th and 20th) I suggested the possibility of converting toxins into antitoxins by oxidising bacterial products with the help of tannic acid and the natural vegetable ferments—oxydases, &c. Will you permit me to draw your attention and the attention of your readers to an abstract of a paper which appeared in the *British Medical Journal* of July 6th? I refer to the Epitome, p. 4, No. 11, "The *Artificial Preparation of Therapeutic Serums.*" It would appear that Czajkowski successfully carried out the suggestion I made, only using the oxidising ferments of the liver and spleen in place of vegetable ferments.

I am, Sirs, yours faithfully,
S. F. WERNICH.
Somerset Strand, Cape Colony, July 29th, 1907.

THE TREATMENT OF INEBRIETY.

To the Editors of THE LANCET.

SIRS,—I send for publication an account of my experience as medical superintendent of the Dadson Nursing Home for Inebriates in Norwich which has been in existence for just two years.

The treatment I have adopted has been a short one of usually four weeks and the results obtained on both men and women have been highly satisfactory. Statistics in a matter of this sort are of no great value but I take the first 50 cases, all of which were treated over a year ago and most of whom have been traced. These cases were all treated on somewhat similar lines and an account of one typical case will show the system which I think should have the consideration of those who have cases of chronic alcoholism amongst their patients.

A man, aged 47 years, entered the home on August 3rd, 1905; he had been a chronic alcoholic for years and had a distinct family history of hereditary alcoholism. I allowed him to have a certain amount of his favourite beverage, as he was drinking heavily on admission, and started him at once on one teaspoonful dose with about two ounces of water added, every two hours from 9 A.M. till 9 P.M., of the following tonic: Ammon. chlor., gr. i.; aloin, gr. ii.; tr. cinchon. co., ʒ iii.; viburnum cordial, ℥ i. Being in a shaky condition I found that an occasional dose of a mixture composed of ammon. chlor., tinct. cinchon. co., viburnum cordial, tr. capsici, and ext. kolæ liq. was very beneficial. I also gave him four times a day at intervals of four hours five minims of the following hypodermic injection: Daturinæ sulph., gr. i.; strych. sulph., gr. ii.; acid. boric., gr. v.; aq. dist., ℥ iv. During the first ten days I increased the injection gradually to double this quantity, no unfavourable symptoms being present. I am of opinion that datur. sulph. is much better than atropine, patients suffering far less from their eyes and complaining less of dryness and parched throat.

The injections and tonics were continued for three weeks and during the fourth week of treatment I reduced the number of tonics and number and quantity of injections, until at the end of the fourth week, i.e., the last day of treatment, he received only two doses of tonic and one five-minim dose of injection. Insomnia was treated by means of veronal.

This man had perfect freedom during his stay in the home. After a few days his desire for alcoholic beverages disappeared and by the end of the first week he was practically normal. His brain began to be active and he was anxious to have occupation. He went straight back to his such codes have their value, and of those who complain that to endeavour to govern the profession by codes agreed upon by the majority is to introduce the taint of trade unionism we would ask:—Can there be any objection to a professional union bent on maintaining in each of its units the highest traditions of an unselfish profession? Should we not all rejoice to see a profession united in its determination that every member shall do all in his power for the good of his patients and nothing that he can avoid that might harm his colleagues? It is such a spirit as this which has always actuated and still inspires the majority of the medical profession. If there is some fear that keenness of modern competition may lead to the introduction of conduct based on the commercial mottoes "caveat emptor" and "the devil take the hindmost," there are also signs that the power of the majority to prevent such conduct is steadily growing. We must teach our students from the outset the great difference which exists between our profession and a trade. He must be trained whilst still at the hospital to look forward to conducting his practice in accordance with the best professional ideals and to participating in movements for the strengthening of all the existing authorities within whose power it is to prevent backsliding in any branch of our calling.

The Scientific Spirit.

Whilst endeavouring thus to adopt the right professional outlook the student must also acquire the true scientific spirit. Briefly this may be defined as the love of truth. The temptation to accept dogma for truth and speculation for demonstration is very great in medicine. The vast advances which are constantly taking place in our science make it above all things necessary that our students should acquire a capacity for judgment rather than a store of so-called facts. The facts of one generation of practitioners, even of one generation of students, are many of them discarded by the next. A man who has acquired a truly scientific spirit will be able to modify his point of view to suit new theories and to adapt his practice to the altered circumstances; the change of front will in his case mean a comprehension of the evolutionary principles of science. He who has merely imbibed the teaching of tradition will be without a guide when the foundations of the tradition are seen to be not truly laid. A medical man must love science for science' sake, and he must desire knowledge for the added power that it gives him to serve his fellow men. Whatever may be the medical school of the student's choice he will surely come in daily contact with men devoting themselves without stint to the search for truth. Whether the search be conducted in the laboratory or in the wards he will find his senior colleagues devoting themselves with equal zeal to the practical application of the truths of medical science to the relief of suffering. Let these men be his heroes and let him decide to carry out in practice the principles he will learn at their feet. Thus will his five years medical education be an education in the truest and highest sense and form a fitting prelude to the practice of a profession which with all its superficial faults remains one of the most satisfactory of human occupations.

THE READING OF THE STUDENT.

It has been our custom for very many years to make a selection among the books dealing with the various subjects of the medical student's scientific and professional education, and this selection has been subdivided usually into two great categories—viz., books recommended for pass examinations and books recommended for honours examinations. The selection of books was made with the coöperation of a representative group of professors, lecturers, and practical teachers in the different medical schools, and was regularly revised from year to year. We believe that so far as it is possible to pick out a library for the medical student that should be of practical use to him we accomplished this task, but we have decided to attempt it no longer. The place of books in the medical curriculum has been steadily altering, until the point is now reached that the only persons who can give valuable advice to medical students as to what books they should buy are those who actually superintend the instruction in the different subjects. The catalogues to be found in all recent issues of the Students' Number of The Lancet enumerate books within whose covers there is contained more—much more—than it can be conceivably necessary for any medical student to know. We have nothing to add to and nothing to subtract from these catalogues. They do not comprise a very large library for an earnest student to read in a curriculum extending over five years, but if the books are read properly they will amply suffice. Whatever care be devoted to the making of a selective list the result will not be always perfectly satisfactory for every student, for there is no work on any subject which is suitable for all candidates and all examinations. Consequently when there are two books of equal standing it may be impossible to say which is the better of the two, and in such cases we have always given the reader a choice of alternatives. But however carefully the attempt be made to choose books for the medical student which may be useful to him in all the emergencies of his educational career, it is bound for the future to be only an attempt. The real work of the medical student is done now in laboratories, in the dissecting room, in the wards, and in laboratories again. Systematic reading, which will certainly render his negotiation of examination tests much more ready, must be done in accord primarily with his own ability to learn from books, and secondarily in response to the advice of his many teachers.

We may, however, usefully give a few general hints on the subject of reading by students. The student has to remember that there are two objects which he should have in view: the first, which is usually looked upon as the more urgent, is the passing of the various examinations which are necessary for the degree or diploma he desires to obtain. The other object is, however, of more importance ultimately, and this is the attainment of a thorough knowledge of his profession so that he may practise it to the benefit alike of his patients and himself. The books which are most suitable for the second object are not necessarily those which would afford most assistance in attaining the first. The examinations must, alas, have the prominent place while he is yet a student, for until he has surmounted these obstacles he is entirely precluded from the practice of his profession. In choosing books for a particular examination the student must avoid both reading too little and reading too much, and it is here that the advice of a teacher or a senior student should be sought. For personal knowledge of the student is necessary before he can be advised in the best way either as to what he should read or as to how he should read it. The greatest danger lies, perhaps, in reading too widely. Many students dip into many books and fail to master any. The student should recognise the scope of his examinations and should first endeavour to limit his reading to the required standing. When, however, he has made himself master of that portion of the subject which the regulations of the examination require he may go farther. A book might be very useful or even necessary for one examination and useless for another of a different standard, and if useless it is really harmful, for its perusal will take up time which might be more usefully employed. The output of volumes from the medical press has increased enormously; but on the other hand, it is every year less and less important which particular work the student selects.

part of some members of the council to make the appoint-nt of a county officer conditional upon the retention of part-time medical officers in the western districts, hough one very prominent member said that in his experi-ce he had seldom found medical officers of health who re independent of the local authorities.

Typhoid Fever in Winchcombe in 1906.

The medical officer of health of Gloucestershire, Dr. J. iddleton Martin, comments in his annual report upon the tbreak of typhoid fever which occurred on Cleeve-hill in e Winchcombe rural district in the autumn of 1906. There ere 39 persons attacked and all the affected houses were pplied with water from two neighbouring sources which ere contaminated about the same time. "The story of this tbreak," says Dr. Martin, "is all the more to be deplored, cause it ought never to have occurred had attention been ven to reiterated warnings."

August 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Proposed Testimonial to Mr. John Carswell.

A MEETING has been called by the Lord Provost of lasgow to consider the desirability of expressing in some angible manner the sympathy felt for Mr. Carswell in con-exion with the recent distressing incident, when he was hot at and seriously injured in the public streets by a man hom he had certified insane some time previously. The neeting was well attended and it was agreed that an attempt hould be made to raise £500 by subscription for presenta-ion to Mr. Carswell. A committee was formed, of which he Lord Provost was appointed convener, Dr. J. Crawford Renton sub-convener, and Mr. Nicol, City Chamberlain, honorary treasurer. The sum of over £60 was subscribed at the meeting.

Enteric Fever at Peterhead.

The total number of cases of enteric fever notified so far since the commencement of the outbreak amounts to 340. Of these 147 have been treated in the hospital and the remainder at home. During the last week 57 cases have been discharged as well and no deaths have occurred. The number of cases notified during the past week has been 16. It is now estimated that out of the total number of cases 180 patients have fully recovered. At a monthly meeting of the Peterhead town council held recently it was agreed to provide hospital accommodation, if necessary, for fever patients from the coastguard buildings and from the Admiralty works, on the same terms as the council is charged for town's patients at Strachen Hospital. At a meeting of the public health committee, held on August 8th, the local medical practitioners were asked to attend for the purpose of making any practical suggestions with a view of an abatement of the epidemic, and the following recommendations were adopted:—

1. That every person suffering from the disease who is without proper lodging or accommodation, or is so lodged that proper precautions cannot be taken for preventing the spread of the disease, should be removed to and detained in hospital so long as he continues in an infected condition.
2. That bi-weekly analyses of the water be taken.
3. That all bedding, clothing, or articles which have been exposed to infection shall be taken to the hospital for the purpose of disinfection.
4. That the services of an expert be obtained for the guidance of the town council, and that Dr. Matthew Hay, medical officer of health, Aberdeen, be appointed.

These recommendations were approved of at the Council meeting.

Nairn Town and County Hospital.

The annual meeting of the Nairn Town and County Hospital was held on August 15th. The medical officer reported that 101 cases had been under treatment during the year. Of these 66 were cured, 19 were relieved, eight died, and eight remained in hospital. 47 out-patients received treatment. The new hospital, which was formally opened on August 15th by the Earl Cawdor, has now been successfully completed. The total cost of the hospital was £4721 11*s.* 2*d.* Towards this Mr. Mann had gifted the sum of £4000, while the free proceeds of the bazaar amounted to £1408 19*s.* 1*d.*

August 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Tuberculosis in Ireland.

THE Registrar-General of Ireland, in his annual report for 1906, points out that while in England the rate for all forms of tuberculous disease has declined from 3·3 per 1000 in 1864 to 1·6 per 1000 in 1905, and in Scotland from 3·6 per 1000 in 1864 to 2·1 per 1000 in 1905, it has in Ireland risen from 2·4 per 1000 in 1864 to 2·9 in 1904 and to 2·7 per 1000 in 1905 and 1906. A decline from 2·9 per 1000 in 1904 for all forms of tuberculous disease to 2·7 per 1000 in 1905 and 1906 is something, but not much. Out of a total of 74,417 deaths registered in Ireland in 1906 no fewer than 11,756, or 15·8 per cent., were due to tuberculous disease. Of the total number of 11,756 deaths the number dying from phthisis (pulmonary tuberculosis) was 8933. Of this total 1072 died from the age of 15 to 20 years, the deaths from 20 to 25 years numbered 1444, and from 35 to 45 years they numbered 1557. The number given as dying between 25 and 35 years is 2573 (1292 males and 1281 females). It is little wonder that the Registrar-General says that, comparatively speaking, Irish people are not alive to the dangers which threaten them.

Queen's College, Belfast.

It will be recollected that Sir Donald Currie gave £20,000 to the equipment fund of Queen's College, Belfast, provided a similar sum was subscribed, which was done, and the college thus benefited by £40,000; he also offered, if the students would try to raise a sum sufficient to purchase an athletic field, to be responsible for a fourth of it. The amount aimed at was £5000, but owing to most inclement weather a bazaar in aid of the fund did not succeed so well financially as was hoped. However, Sir Donald Currie, on hearing this, most generously sent last week a cheque for £2000 to pay off the amount required to complete the £5000. This splendid act of generosity has given the most profound satisfaction in Belfast circles. At the request of the authorities of Queen's College Lord Kelvin has kindly consented to come over to Belfast for the purpose of opening the new buildings, which are to be devoted to scientific research and teaching. The ceremony is to take place on Sept. 20th.

Health of Belfast.

For the week ended August 10th 20 cases of infectious disease were notified in Belfast: four of typhoid fever, two of scarlet fever, four of simple continued fever (whatever disease this is), one of diphtheria, four of erysipelas, and five of cerebro-spinal fever. This number is less than that of the previous two weeks which were 27 and 32. There is an increase of two in the case of cerebro-spinal meningitis. The death-rate was low—14·6. There were three deaths from cerebro-spinal fever.

Alleged Pollution at Stoneyford.

The question of the pollution at Stoneyford, one of the Belfast water catchment areas, came before the Lisburn Rural Council on August 17th, when the solicitor of the council reported that by the instructions of the council, in company with Mr. J. Midgley-Taylor, C.E., London, and Mr. R. Best, barrister-at-law, he visited the Forked-Bride filter-beds to inspect the works and the grievances from which the people of the district alleged they were suffering. The caretaker at the filter-beds refused them admittance on the ground that they had no order. They were then obliged to make a circuit round the farms and through the meadows adjoining, with the caretaker in close attendance. In the opinion of the solicitor, the conduct of the Belfast Water Commissioners was "both stupid and childish and totally unbecoming a public body, for if they were satisfied that they were not at fault they should not only allow an inspection, but in fact court one to allay the feelings of the public in regard to the matter." A further report was made to the council (which is the sanitary authority of the Stoneyford area) of the foul nature of the liquid passed from the sand-washing operations into the Killultogh River. The council decided to engage the services of a competent man to keep watch and to report full particulars as to the mode of discharging the sediment and water into the river from the filter beds. The whole question of the condition of the Stoneyford area is of much importance, and the report of the

THE STUDENT'S GUIDE.

SESSION 1907-1908.

A PREFATORY STATEMENT.

THE quantity of the subjects which fall necessarily within the scope of our educational number has now become very large, and it may be as well to explain the scheme upon which the following guide to a medical career in this country is constructed.

The General Council of Medical Education and Registration, conveniently known as the General Medical Council, is the controlling authority, under the Privy Council, of the medical education of the land. Under the provisions of the Medical Acts various universities and corporations are recognised as being examining bodies whose degrees or diplomas entitle to medical registration, and it is among the duties of the General Medical Council to keep the official register and to insure by periodical visitations that the tests of the various examining bodies are maintained at a due standard. We begin by detailing the powers of the General Medical Council, and go on to give in detail the regulations of the various examining bodies.

But the student must be taught as well as examined, and the systems under which he can obtain instruction do not conform to one pattern. The curriculum of the medical student falls into two parts, the preliminary subjects and the professional subjects. The two cannot be sharply divided—for example, to which does materia medica belong? The extent to which they are allowed to overlap under different schemes of education varies a good deal, while the extent to which they ought to overlap is a perennial subject of debate. The preliminary subjects are, to mention only the four important ones, chemistry, biology, anatomy, and physiology, and they are taught in the school proper; the professional subjects, medicine, surgery, and obstetric medicine—under which headings all forms of specialism are included—must be learned in the wards of a hospital. All schemes of medical education require a school and a hospital, but there their uniformity ends.

There are nine universities in England, four in Scotland, and two in Ireland which possess a faculty of medicine. They are prepared to educate their students to a varying extent, or to delegate the preparation of their candidates to other recognised bodies; they then examine their students, generally and in England invariably, with the help of examiners brought in from other medical centres, and bestow degrees in medicine upon the successful candidates. We give the regulations of these universities and follow with those of the Royal Colleges of the three divisions of the United Kingdom, of the Society of Apothecaries, and of the Apothecaries' Hall of Ireland.

From this point we pass to the consideration of the hospitals at which the latter part of the medical training of the students must be received. The students at these hospitals may look to the hospital medical school for the whole of their training, as, for example, the student working for the diploma of a corporation would generally do; or they may be taking out a clinical course at the hospital, intending to graduate at one of the universities. In a sense, therefore, the medical school and wards of every hospital form part of a university, by supplying an integral section of the teaching required by the university from candidates for medical graduation; and this has been recognised in the reconstitution of the University of London under which all the medical schools of the metropolis are affiliated to the University of London.

Detailed information concerning all the medical schools and their hospitals naturally forms the bulk of the STUDENTS' NUMBER of THE LANCET; but we follow upon this with an account of the condition of medical employment in the Naval, Military, and Indian Medical Service, and in the Public Health Service, concluding with a report upon the system of education in dental surgery.

We think that the reader with this brief prefatory statement before him will know where to look for any subject upon which he wants enlightenment.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

POWERS AND DUTIES OF THE GENERAL MEDICAL COUNCIL.

As there is apparently, even among members of the medical profession, a great amount of ignorance as to the powers and duties of the General Medical Council, we think it well to lay clearly before our readers what the General Medical Council is and also what it is not.

Many of the false ideas on the subject are due to the use of the shortened title, "General Medical Council." The full title is, "General Council of Medical Education and Registration of the United Kingdom." This title is in accordance with the Medical Act of 1858, by which the General Medical Council was established under the Privy Council to enable persons requiring medical aid to distinguish qualified from unqualified practitioners. The Council was thus instituted not primarily for the benefit of the medical profession but to insure an efficient medical service to the public. It is obvious that by so doing the profession itself gained, in that official sanction was given to reputable practitioners only, while a proper guarantee was afforded to the public that the standard of medical education should always keep abreast of the scientific knowledge of the day. The powers of the Council under which it fulfils these important functions fall under four heads. It is first a registering body: it registers the entry of students upon their medical studies and also the attainment by them of the degrees or other qualifications that legally entitle them to practise medicine. This last duty forms its chief service to the State, as a complete list of practitioners of legal standing is thus rendered available for the information of the public. Secondly, it assures the public that the education of medical men is kept up to an efficient standpoint by maintaining at the proper pitch the standard of the various medical examinations. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner adjudged guilty of conduct "infamous in a professional respect." Here again it is the public interest that is first considered, although these powers are for the very material advantage of the medical profession. The last duty of the Council is the codification of pharmaceutical remedies, and it may be mentioned that the periodical sale of the British Pharmacopœia is a source of income that does much to insure the Council's solvency. Reform in the administration of the finances of the Council has of recent years removed acute pecuniary strain from that body, but the day should soon come when the State, recognising the public value of the work of the Council, should be willing to subsidise its efforts. Registrars are appointed by the General Council and by the Branch Councils to keep registers of qualified persons. They are bound by Section XIV. of the Act to keep their registers correctly, a duty which, mainly owing to the apathy of members of the medical profession, can only be performed with difficulty.

It is as well here to put down the advantages, such as they are, of being duly registered. A duly registered practitioner may sue in the courts of law for the recovery of charges for medical attendance or advice, or surgical attendance or advice, or for the supply of medicine, or for the performance of any operation—provided that he is not debarred from suing by being a Fellow or a Member of any corporation which objects to its Fellows or Members so suing. He may be exempted, if he so desire, from serving on juries, from serving sundry corporate and parochial offices, and from serving in the Militia. Only a registered practitioner can hold appointments in the navy, army, and in sundry Poor-law and other institutions. Only a registered practitioner can sign a valid medical certificate. Removal of the name from the Register debars a man from all the above-mentioned privileges.

remarks hold true for other malarial districts of the Peninsula and adjoining islands. A vast amount of work still remains to be done, however, before Italy can be freed from her perennial scourge. This must be accomplished not only by better organisation of the sanitary services against malaria but by coördinating the task of the medical man with that of the engineer and that of the agriculturist.

The Lunacy Laws in Italy.

A question having been put to the President by one of the councillors of the provincial deputation of Rome regarding the case of a man lately discharged from the lunatic asylum as cured, but who had subsequently committed suicide in prison during a recurrence of suicidal mania, Professor Mingazzini, medical superintendent of the asylum, has addressed a letter to the president of the deputation calling attention to the state of the law which renders such occurrences possible. The law of Feb. 14th, 1904, clearly prescribes that only those lunatics who, in addition to showing signs of mental alienation, are in some way giving rise to public scandal, or are dangerous to themselves or others, shall be definitely interned in asylums. It thus becomes the duty of the medical authorities to reject as ineligible the harmless idiot, the epileptic who is subject to maniacal attacks only at long intervals, the alcoholic who, immediately he escapes from the toxic action of alcohol, regains his usual calm, and finally all delinquents who, even though completely destitute of moral sense, do not exhibit the clinical symptoms required to raise their moral blindness to the level of recognised insanity. The asylum, in other words, must, according to the spirit of this law, be reserved for dangerous or unmanageable lunatics, and the director of the institution has no alternative but to discharge an inmate who has temporarily recovered, even when his mental condition is such as to forbode within a more or less distant period of time new and still more terrible manifestations of his latent malady. For example, if an epileptic who during an access of mania has attempted or even committed homicide remains perfectly free from further attacks for some months or at most one year, it becomes the legal duty of the director to order his discharge from the asylum. A similar thing happens to the alcoholic who after some months of abstinence, during which he regains his mental lucidity, is dismissed as cured, although it may be easily foreseen that once set at liberty he will inevitably yield to the imperious call of the drink habit. While the asylums of Italy thus shut their doors against all but the dangerous lunatic, where and by whom, asks Professor Mingazzini, are received the 60,000 epileptics whom the asylums cannot admit, the idiots, the harmless imbeciles, the constitutionally abnormal adolescents (who in Italy are more numerous than in any other European country), and all those poor old demented and paralysed creatures who are stamped as dangerous, albeit their dangerousness consists solely in the expense which their maintenance entails upon their respective families? Thrown into prisons and houses of correction or driven by illness into the wards of hospitals, these poor wretches have nothing before them but homicide, if they are endowed with the criminal temperament, or suicide if they are incapable of the struggle for existence. He urges that such institutions as have lately been established in Germany be provided for the reception of the numerous family of destitute neurasthenics who if not so taken care of become candidates for suicide or crime. Professor Mingazzini is, he adds, ashamed to think that the only asylum of which Rome can boast owes its existence to the piety of a Pope, and that the provincial deputation, after deliberating for some 20 years, has not been able to decide where to place the first stone, not of such a beneficent institution as that which he advocates, but even of a commonly decent lunatic asylum of which everyone admits the city's urgent need.

August 13th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Criminal Responsibility of the Insane under the New Civil Code.

As the Austrian Civil Code is just now under reconstruction Professor von Wagner, the eminent professor of psychiatrica, in a paper recently read before the Society of Neurology and Mental Diseases, dealt with the question of reforming the present laws dealing with the responsibility of the mentally afflicted. The professor emphasised the necessity of amending the present conditions as these allow the judge too little liberty in forming his opinion as to the causes for not punishing a criminal of this type. In fact, the law is so narrowly drafted as to extend the exemption from punishment to such persons only as are entirely devoid of reasoning, individuals who are usually incapable of doing any harm. Therefore the present tendency is for judgments to go further than the law strictly allows. Professor von Wagner therefore advised the formulation of positive principles, stating *the types of mental diseases* which affect the evil-doer in such a way as to render him *incapable of distinguishing between right* and wrong and the types which have not this effect. That constant source of dispute between lawyers and psychologists, moral insanity, could also be brought into the positive part of the text. The Austrian law does not fix the position of the psychiatric expert, and leaves the judge who, as a rule, has no special knowledge in this respect, to decide the fate of mentally afflicted persons when they have come within reach of the law. Professor von Wagner thinks it advisable therefore to appoint experts with a consultative vote, and to erect special institutions where the mentally afflicted criminal can be placed under continuous observation of both the mental experts and the legal authorities. Such homes for insane criminals are contemplated already by the Government, as is shown by the budget of the Minister of Justice. Special care ought to be paid also to mentally affected children, as from these a number of criminals spring, who could be prevented from doing harm to the public if taken care of in proper time. The proposal of Professor Wagner will be brought before the next congress of psychological medicine, and if adopted will be presented to the Government as a basis of reform in this particular respect.

Late Opening Hours in Shops.

An important step in the social improvement of the hard-worked shop assistant has been made by the almost universal adoption in Vienna of early closing hours for the shops of all descriptions. It was at first proposed to close these shops early enough to release the staff at 6 in the evening, but business interests suggested that people want to shop up to a later hour, so that 7 or 8 o'clock, according to the kind of business, has been agreed upon. But now the matter has been taken in hand by medical circles and it is possible that this reform will be reformed again. It has been justly emphasised that the desired effect of this measure, the possibility of open-air recreation, is not at all attained by finishing the day's work early in the evening, as there is only little fresh air to be had at that time in large towns or cities. The smoke and dust produced by the factories and the traffic is just as bad at 6 as at 8. The proper way to attain the object would be late *opening* of the shops at 9 o'clock, with special necessary exceptions, of course. This would allow the staff to obtain an ample supply of fresh air before coming to the shop, as in the morning the air is nearly always pure. The present opening hour is 7.30 A.M. This suggestion has aroused much interest in the parties concerned and it is possible that for once at least they will be on the side of common sense.

Alcohol and Mental Disorders.

By investigations made to ascertain the influence of alcohol on the mental faculties certain facts have been elucidated which are well worthy of mention. In a report from the asylums for the insane of Austria covering the last decade 70,000 insane were dealt with, and in about 15 per cent. of these alcohol was the chief or contributing cause. The one drawback to this calculation is the fact that hereditary influence is not considered. Numerous cases of alcoholic parents without mental disorder are known who beget insane children who do not fall victims to alcoholic excesses. As a rule alcoholic parents are fairly prolific, but their offspring suffer from mental defects, and the third generation, if alcohol is still indulged in, are no more capable of procreation. Great care must be exercised in eliciting all the facts concerning the parental alcoholism. In a series of 392 alcohol-insane inmates of the Vienna lunatic asylum 80 per cent. had hereditary influences to explain their lessened resistance to the toxic effect of alcohol. Another very interesting series showed the rule that when the primary criminal drunkard begets children they come in conflict with the laws oftener than the parent, whilst *their* children, few in number, generally become a burden not to the funds of the

UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as a purely examining and degree conferring body with several affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament 1898 and became a teaching body. Many schools already existing became constituent colleges, including all the metropolitan medical schools. It is necessary that the teachers in these should be recognised and approved by the Senate as conducting work of university rank, and in this way the University may be said to have benefited the whole of medical education in London. It also appoints teachers in special subjects to give lectures at the University and the question of a further centralisation of preliminary scientific studies is at present occupying the very serious attention of the University and its constituent schools. The medical degrees awarded by the University are those of M.D., M.S., and M.B., B.S., the two latter being now given together as a graduating degree, whereas formerly the M.B. alone was a qualifying degree and the B.S. was taken optionally as a separate examination.

The Matriculation Examination.—The examinations take place three times in each year—namely, on Sept. 15th (if that day be a Monday, or if not, on the Monday next preceding the 15th), on the second Monday in January, and on the second Monday in June (or July, as may be hereafter determined). The examinations in January and June (or July), but not that in September, may be held not only at the University of London, but also, under special arrangement, in other parts of the United Kingdom or in the colonies. Every candidate must, on or before August 24th for the September examination, on or before Nov. 25th for the January examination, and on or before April 25th for the June (or July) examination, apply by postcard to the Principal for a form of entry, of which the first in order must be returned 14 days before the commencement of the September examination, the second on or before Dec. 1st, and the third on or before May 1st, accompanied in the same cover by a certificate showing that the candidate has completed his sixteenth year, and by his fee for the examination. A certificate from the Registrar-General in London or from the superintendent registrar of the district, or a certified copy of the baptismal register, or a declaration of the candidate's age, made before a magistrate by his parent or guardian, or by the candidate if of full age, will be accepted. As candidates cannot be admitted after the list is closed any candidate who may not have received a form of entry within a week after applying for it should communicate immediately with the Principal, stating the exact date of his application and the place where it was posted. Every candidate must pay a fee of £2. If he withdraws his name before the last day of entry it shall be returned to him. If he fails to present himself he shall be allowed to enter for a subsequent Matriculation within eight months on payment of £1. If he retires after the commencement of the examination or fails to pass it the full fee of £2 shall be payable on every re-entry. Candidates must show a competent knowledge of each of the following five subjects, according to the details specified: 1. English—Composition, Précis-writing, salient facts in English History and Geography. 2. Elementary Mathematics—Arithmetic, Algebra (including quadratic equations and graphs of simple functions), and the subjects of Euclid (Books I. to IV.). 3. Latin, or Elementary Mechanics, or Elementary Physics (Heat, Light, and Sound), or Elementary Chemistry, or Elementary Botany. 4 and 5. Two of the following subjects, neither of which has been taken under Section 3 (if Latin be not taken one of the other subjects must be another language from the list): Latin, Greek, French, German, Ancient History, Modern History, Logic, Physical and General Geography, Geometrical and Mechanical Drawing, Mathematics (more advanced), Elementary Mechanics, Elementary Chemistry, Elementary Physics (Heat, Light, and Sound), Elementary Physics (Electricity and Magnetism), and Botany. Additional subjects, of which, however, candidates must give notice two months previous to the examination, are: Arabic, Sanskrit, Spanish, Portuguese, Italian, Hebrew, and Zoology. A pass certificate signed by the Principal is delivered to each successful candidate after the report of the examiners shall have been approved by the Senate.

Internal and External Students.—Students of the University may be either internal or external. Internal students are those who have matriculated at the University and are studying in a school or schools or under one or more of the teachers of the University. The medical schools in question are those connected with University College Hospital, King's College Hospital, St. Bartholomew's Hospital, the London Hospital, Guy's Hospital, St. Thomas's Hospital, St. George's Hospital, the Middlesex Hospital, St. Mary's Hospital, Charing Cross Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine and the Lister Institute of Preventive Medicine are also recognised as schools of the University in special departments. External students are those who undertake approved courses of study at schools recognised by the University but not belonging to it.

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations and are carried on simultaneously with the examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any provincial centre must give notice upon their forms of entry to the Principal of the University, who will then make all necessary arrangements. Besides the University fee, a fee usually varying from £1 to £3 is charged by the local authorities and must be paid *at the local centre* immediately before the commencement of the several examinations.

Bachelor of Medicine and Surgery.—Every external candidate for the degree of Bachelor of Medicine and Surgery will be required—1. To have passed the Matriculation examination in this University not less than five years previously. 2. To have passed the Preliminary Scientific examination Part I. (Inorganic Chemistry, Physics, and Biology) not less than nine months after Matriculation, and the Preliminary Scientific examination Part II. (Organic Chemistry) not less than six months after Part I. 3. To have been engaged in his professional studies during five years subsequently to Matriculation and four years subsequently to passing Part I. of the Preliminary Scientific examination at one or more of the medical institutions or schools recognised by this University, one year at least of the four being spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine. In order to be admitted to the Bachelor's degrees internal students are required—1. To have attended prescribed courses of study in one or more schools of the University for five years after registration as internal students. 2. To have passed Part I. of the Preliminary Scientific Examination not less than one year after Matriculation, and Part II. of the same examination not less than six months after Part I. 3. To have passed two examinations in Medicine.

Preliminary Scientific Examination.—The Preliminary Scientific Examination, Part I. (Inorganic Chemistry, Physics, and Biology), will take place twice in each year, commencing on the third Monday in January and on the second Monday in July. It must be passed by internal students not less than one academic year after matriculation and by external students not less than nine months after matriculation. Every candidate must apply (internal students to the academic registrar and external students to the external registrar) for a Form of Entry on or before May 24th or Dec. 5th, which must be returned, accompanied by the proper fee, not later than June 1st for the July examination or Dec. 12th for the January examination. The fee is £5 for each entry to the whole examination, provided that all the subjects are taken at one time. When less than the whole examination is taken at one time it is £2 for each subject. The examination will include papers, practical work, and oral questions on Inorganic Chemistry, Physics, Botany, and Zoology. Candidates must present themselves either (1) in Inorganic Chemistry, Physics, and Biology; or (2) in Inorganic Chemistry and Physics; or (3) in Biology. If they fail in any one subject they may present themselves for re-examination in that subject alone, provided that if they fail in both inorganic chemistry and physics they must present themselves for re-examination in these two subjects taken together. Part II. of the Preliminary Scientific Examination will take place twice in each year, commencing on the Thursdays following the third Monday in January and the second Monday in July. No candidate will be admitted to this examination within six months of having passed

Penzance and he will be much missed there, and great sympathy is felt for his widow and four children. The funeral took place at Illogan churchyard on August 10th and was largely attended.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Georg O. Kirchhoff, the senior member of the profession in Germany, being 94 years of age. Up to the year 1900 he held an appointment as district medical officer in Leer, Hanover.—Dr. Josef Jacobi, formerly titular professor of pharmacology in Breslau and author of various papers on that subject, as well as on hygiene and ophthalmology. He was 67 years of age.

Medical News.

UNIVERSITY OF EDINBURGH.—The following is the official list of passes at the recent professional examinations for degrees in medicine and surgery:—

First Professional Examination.—George M. Adam, William J. Adie, Joseph R. Aeria Robert Aitken, John E. Allan, Wallace R. Bayne, Henry Bedingfield, Delvine Bell, Archibald J. Bennee, Alexander G. Biggan, Herbert F Blacklee, John P. Blockley, Arthur Bloom, Norman H. Bolton (with distinction) Thomas C. Britton, Niels H Brönnum David L. Brown, William Bruce, Cecil Bur ham, A. Bruce Cheves, Jacob D. M. Claassens, Effie M. D. Craig, Philip L. Davies, Charles G. Deane, Robert C. Dickson, John M. Drew, B.A., Helen C. Dykes, Abraham Eprile Joseph Geoghegan, John M. Gillespie, Robert Govan, M.A., John V. L. Grant, William C M Grant, James Gray, John W. Gray, M.A., Albert Groenewald, Spencer M. Hancox, Kenneth G Hearne, Alfred M. V. Heaterlow Stewart Hodgson, J. Elise Hoffmann, Harry F. Holmden (with distinction), Gwendolyn G. Hunter, William H. Inch, Robert C. Irvine, William H Johnston, B A., Braj B Kapila, Edward W Lawrence, George L. Leggat, Louis Levy, William E. Lewis Neale L Lochrane, Henry R. Longstaff, Adrian H. Louw, Francis R. Luke, George M'Connell, Ian Macfarlane, Alexander M. Mackay, Jessie A. MacLaren, Francis de S M'Menamin, L. B. C. Marksman, Seal Marshall, John S. S. Martin, Victor H. Mason, Horace M. Mills, Archibald B Mitchell, John S. Monro, Arthur E. Moore, Hugh Morris, B A., John T. Morrison (with distinction), R Carlyle Moses Thomas P. Noble, Patrick F. Nolan, Robert Park, Harold H. Proudfoot, Nicholas Purcell Maxwell Ramsay, Mary D. Rankine, Spence D Reid, George Richardson, John S. Robertson, John Scott, Peter M L. Shiels, Bryce M. Smith, Charles E H. Smith, Jacobus J. Stander, Robert S Stevenson, Samuel D Stewart, Sidney W. H Stuart, Tehl Singh, Dirk L. Theron, Arthur H. Towers, Patrick G. Touhy, Peter Vieyra, Gerritt H. W. de Vos, Charles D. Walker, Chung Ching Wang, Hermann W. Webb, James B. Wilkie, Donald M'D. Wilson George Wilson and Walter Q Wood.

Second Professional Examination.—Fergus Armstrong, Janet Armstrong, Anédée E. C Beausoleil, John Henry Bell, Ronald A. Bell, Jackson G. Boal, William G. Brand, Peter de Bruyn, Oswald S Bulloch, Armando D Child, James Davie, William N. Davies, Alexander B. Dryman, William Dunlop, Alexander H. Elmslie, Herbert G. Feltham, Gerhard F Fismer, Michael Gavin, Frederick P. Gibson, Walter E Goss, William T. Graham, Robert Hamilton, Thomas E. Harwood, B.A., Eduard B. Hoffman, John H. Jones, Roy B. Kerr, Changathara G. Kurien, Lina Kurz, Janet Leiper, Leonard Leslie John S. Lerack William H. Lowe, Donald C. Macaskill, M A., Margaret M'Cahon, Patrick M'Cool, James M'Hall, M.A., James M C. M'Keand, Neil M'Leod, Mary M'Millan, Hector D. MacPhail, M A., Andrew J. Macrie, Charles G. Marais, Alexander F. W. Millar, Gregor M. Miller, Alexander M K. Minford, William Morrison, Rhoda May Murdoch, William J. Nisbet, James E. R Orchard, Horace R. A. Philp, Johannes A. Pienaar, B.A., Ella F. Pringle, Frederick W. Rayment, Charles S. Sandeman, John M G. Scott John D. Skinner, William Stevenson, Arthur E Tait, Robert H. Tait, Leonard W. O. Taylor, Seymour Williams, and Margaret C. Young.

Third Professional Examination. A. H. T. Andrew, William Bainbridge, A. R Bearn, Henry Burns Ellison Canefield, J. A R. Cargill, H G Carter, Louis L Cassidy, P. H. Chauvin, A. C. Court, J. C. Craig, M A., John Crocket, J M. Dalrymple, Margaret E. Davidson, Porter Davies, Fred Dillon, Helen Forbes, W. T Gardiner, A. B. Gordon, W B Grant, J. O. Hamilton John Hewat, K. R. K Iyengar, William P. S Johnson, James Langwill, Robert D. Laurie, Archibald R. Leggate, Charles L. Louw, Alexandra B. MacCallum, David M Carrol, Ranald MacDonald, George M. Mackay, M.A., Walter J M Keand, David L. MacKenna, John C. Mackenzie, Alexander K Maclachlan, Alexander G MacLeod, Ada J Macmillan, Eva Meredith, Flora Morrison, Anna L. Muncaster, Kishanlal Nehru, Neil S Neill, John G. Nicholson, M A., Hilda M Northcroft, Percy G Palmer, Alfred A. W. Petrie, Bernard P. Phillips, Alfred R. Price, Donald Ross, Marguerite C. Ross, Herbert M. Spoor, Norman G. Thornley, Mary M. M'C. Turpie, David R. P. Walther, George S. Williamson, and Gordon Wilson.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. B. Rawitz, *privat docent* of Anatomy, and Dr Klemperer, *privat-docent* of Medicine, have been granted the title of Professor.—*Budapesth:* Dr. Karl Helm has been recognised as *privat-docent* of Children's Diseases.—*Chicago (Rush Medical College):* Dr. Robert R. Bensley has been appointed Professor of Anatomy and Dr. Edwin O. Jordan Professor of Pathological Anatomy and Bacteriology.—*Cincinnati (Miami Medical College):* Dr. Magnus A. Tate has been appointed Professor of Midwifery in succession to Dr. William H. Taylor who retires.—*Clausenberg:* Dr. B. Gármán has been recognised as *privat-docent* of Medicine.—*Greifswald:* Dr. Georg v. Voss has been recognised as *privat docent* of Psychiatry.—*Halle:* Dr. Ernst Siefert has been recognised as *privat-docent* of Psychiatry.—*Kiel:* Dr. Kulbs has been recognised as *privat-docent* of Medicine.—*Leipsic:* Dr. Dependorf of Jena has been appointed Extraordinary Professor of Odontology.—*Naples:* Dr. Alfredo Gatti has been recognised as *privat docent* of Ophthalmology.—*New York (College of Physicians and Surgeons):* Dr. Francis Huber has been appointed Professor of Medicine, and Dr. Frederick Peterson Professor of Psychiatry.—*Padua:* Dr. Giuseppe Astolfoni has been recognised as *privat docent* of Materia Medica and Pharmacology.—*Würzburg:* Dr. Faust of Strasburg has been appointed Professor of Pharmacology in succession to Dr. Straub who goes to Freiburg.—*Yale:* Dr. J. M. Flint of the University of California, San Francisco, has been appointed Professor of Surgery in succession to Dr. W. H. Carmalt who retires.

THE DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.—The report of the annual meeting of the subscribers to this charity, which was held on July 30th under the chairmanship of the Duke of Portland, shows that the affairs of this useful and national charity are in a very satisfactory condition. The noble chairman, in his opening address, after referring sympathetically to the illness of the Duke of Devonshire and to the deaths of other prominent supporters of and workers in the hospital during the past year, paid a tribute to the 20 years of useful work rendered to the hospital by Mr. A O Haslewood, one of the honorary medical officers, who has recently retired. He then announced that the year had been a record one both in the number of patients treated and in the amount of subscriptions received. The patients numbered 3575 of whom 3295 were in-patients and 280 out-patients, and a sum of £3862 had been contributed by the general public. This increase in work had led to the acquisition of two houses for the purposes of a nursing home. The chairman then referred to the very wide area, practically the whole of England, from which the patients are drawn, and whilst thankfully acknowledging the support of the public urged that as there was still a slight adverse balance against the hospital, owing mainly to improvements, there should be still further increase in the subscriptions. He spoke with indignation of the many applicants for tickets who could themselves afford to subscribe to the hospital, and bore testimony to the enormous benefit that it confers on the class for which it is intended—the suffering poor. He moved the adoption of the report, which Mr. Drewry seconded. The Duke of Rutland moved the vote of thanks to the trustees, the committee of management, and the honorary officers of the hospital, and Sir Squire Bancroft proposed a vote of thanks to the chairman, which votes were carried with acclamation.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. T. M Dolan, M D Durh., J.P., was presented on Aug. 16th at the Halifax workhouse with an illuminated address and a silver rose bowl by the Poor-Law officers and staff of the Halifax union. Dr. Dolan, who has been medical officer to the workhouse for 38 years, is now convalescent from a serious illness, and his colleagues and the staff of the Halifax union chose the eve of his return to active work as an appropriate time to mark their esteem for him.

THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH.—The Rockefeller Institute for Medical Research, New York, has adopted the following series of titles for its staff: Member, Associate Member, Associate, Assistant, Fellow, and Scholar of the Rockefeller Institute, and has made the following list of appointments: Simon Flexner, Member of the institute and director of the laboratories (pathology); S. J. Meltzer, Member of the institute (physiology and pharmacology); E. L Opie, Member (pathology); P. A. Levene, Member (biological chemistry); Hideyo Noguchi, Assistant (pathology); John Auer, Assistant (physiology); Alexis Carrel, Assistant (experimental surgery); J. W. Jobling, Assistant (pathology); Nellie E. Goldthwaite, Assistant (chemistry); C. M. A. Stine, Fellow (biological chemistry); Donald Van Slyke, Fellow (biological chemistry); Martha Wollstein, Fellow (pathology); Maud L. Menten, The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Midwifery and Diseases of Women and Children.

It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne. Candidates who have passed the First and Second Examinations of the University will be exempt from First and Second Examinations of the Conjoint Board.

For the degree of *Bachelor in Surgery* every candidate must have passed the examination for the degree of Bachelor in Medicine of the University of Durham and must have attended one course of lectures on Operative Surgery and one course on Regional Anatomy. Candidates will be required to perform operations on the dead body and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of *Master in Surgery* candidates must not be less than 24 years of age and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in one of these subjects at the Matriculation Examination for the M.B. degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Surgery, in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The subjects of examination are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

For the degree of *Doctor in Medicine* candidates must be not less than 24 years of age and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in one of these subjects at the Matriculation Examination for the M.B. degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor in Medicine of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Medicine in attendance on the practice of a recognised hospital, or in the military or naval services, or in medical and surgical practice. Each candidate must present an essay prepared entirely by himself, which must be typewritten, based on original research or observation, on some medical subject selected by himself, and approved of by the Professor of Medicine and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum so far as they are related to the subject of the essay.

Doctor of Medicine (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under 40 years of age and shall have been in active practice for 15 years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession, and if they have not passed an examination in Arts previously to the Professional Examination in virtue of which they have been placed on the Register, they shall be required to pass in Classics and Mathematics. Candidates who have passed an examination in Arts previously to being placed on the Register are required to pass an examination in Latin. They will be examined in the Principles and Practice of Medicine, including Psychological Medicine, Hygiene, and Therapeutics, the Principles and Practice of Surgery, Midwifery, and Diseases of Women and Children, Pathology (Medical and Surgical), Anatomy (Medical and Surgical), Medical Jurisprudence, and Toxicology. The fee will be 50 guineas, of which 20 guineas will be retained if the candidate fails to satisfy the examiners.

Candidates for any of the above degrees must give at least 28 days' notice to Professor Howden, Secretary, College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays six weeks before the date of the examination.

Professors—Medicine: Sir G. H. Philipson, D.C.L. Surgery: F. Page, M.D., F.R.C.S. Physiology: T. Oliver, M.D. Anatomy: R. Howden, M.B. Comparative Pathology: G. R. Murray, M.D.

ARMSTRONG COLLEGE, NEWCASTLE.—Professors—Physics: H. Stroud, D.Sc. Chemistry: Phillips Bedson, D.Sc. Natural History: Assistant Professor, A. Meek. Botany: M. C. Potter, M.A.

THE VICTORIA UNIVERSITY OF MANCHESTER.

Matriculation, which consists in signing the University Register, must precede entry upon any course of study. Those only can matriculate who are registered students of the University.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

All candidates for degrees in Medicine and Surgery are required to pass an examination called the Matriculation Examination (Faculty of Medicine), or to have passed such other examination as may be recognised by the University for this purpose.[1]

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University and one year at least having been passed in the University subsequently to the date of passing the First M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations: the First Examination, the Second Examination, the Third Examination, and the Final Examination.

The First Examination.—The subjects of examination are as follows:—(1) Chemistry; (2) Physics; (3) Biology; (4) Materia Medica. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into three parts: Part 1, Physics and Chemistry; Part 2, Biology; Part 3, Materia Medica; and the candidates may pass in these parts separately under certain conditions.

The Second Examination.—The subjects of examination are as follows:—(1) Anatomy; (2) Physiology, including Physiological Chemistry and Histology. Candidates may pass in (1) and (2) separately under certain conditions.

The Third Examination.—(1) Pathology; (2) Pharmacology and Therapeutics; (3) Hygiene. These subjects may be taken separately under certain conditions.

The Final Examination.—The subjects of examination are as follows:—(1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Midwifery and Gynæcology (including Practical Gynæcology); (4) Forensic Medicine (including Toxicology). These subjects may be taken separately under certain conditions.

Candidates for the Final Examination must have completed the fifth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or as had been done during the last 11 years in dealing with the regulations for the import of food and the shipping trade. With regard to the necessity for the regulations, he had been asked what would be done in the case of mineral waters. He would point out that in the East-end of London certain classes of mineral waters were made under such conditions that honourable Members, when they realised what these were, would agree that these waters should be brought within the scope of the Bill. The right honourable gentleman went on to refer to a case where the work of manufacture was carried on by a foreigner in Stepney in a yard beside a water-closet. The water was exposed to filthy contamination and some of the bottles had masses of matter in them that looked like mould. Several times last summer bottles filled on these premises had been returned by customers, and when Stepney people complained of bottles being dirty they were very dirty indeed. Frequently it happened that a person rented two rooms and started a mineral water factory. There was no machinery so that the place was not a workshop and it was not a factory. The sanitary conditions for the inmates might comply with the conditions of the local sanitary inspector but no other inspector had any power over premises of this kind. What the Local Government Board wanted to do was to supplement the powers of the local medical officer of health so that he might see that the conditions were not fraught with danger to the people engaged and to the consumers. He had been asked whether under this Bill it would be possible for a medical officer or an inspector to go into any kitchen. He would ask honourable members' attention as to the necessity of anyone going into a kitchen. In the district of what was supposed to be one of the best local authorities in the country there were restaurants where food was prepared for consumption and sale. In these the water-closet accommodation was reported to be in a defective condition and in 35 cases the water-closet communicated with the kitchen, and in some cases the water-closet was off the kitchen without ventilation. If the water-closet itself satisfied the sanitary inspector he had no power to prevent the preparation, storage, and distribution of food. They had, in London, districts where some of the choicest morsels and most expensive classes of food and drink were prepared in conditions which were absolutely intolerable and abominable. He had been asked what organisation was going to be resorted to for carrying out the regulations. The Local Government Board did not intend to create any new organisation. They did not intend to do anything in derogation of what any sanitary authority had the power to do. They intended to act through the existing medical officers and the local authorities for the purpose of enforcing these regulations. The local authorities with their existing staffs and their present expenditure would be able to do this work concurrently with much of their sanitary work. The Local Government Board did not intend to use these regulations as a means of harassing any trader or manufacturer in carrying on his business in a decent way. After the scandals which had been revealed in the last year or two the Board would not be doing its duty unless it sought for the powers contained in the Bill, and he asked honourable members to trust the Board in the regulations which were made under it. It was not intended that the Bill should apply to private houses.

---

[1] The following examinations are accepted in lieu of this:—1. The Board will grant exemption from the Matriculation Examination to graduates of any university of the United Kingdom, provided Latin has formed part of one of the degree examinations. 2. For particulars of the conditions under which holders of Certificates from the Universities of Oxford and Cambridge are entitled to exemption, the Calendar of the Joint Matriculation Board should be consulted. 3. Provided that the Certificate shows that all the subjects required by the General Medical Council have been included, the Board is prepared to receive applications for exemption from persons who hold Certificates of having passed the London Matriculation Examination. The fee for registering external Certificates when exemption is granted is £1

Mr. GRETTON having withdrawn his amendment,

Mr. JOHN BURNS moved an amendment to make it clear that the Bill should not apply to ordinary private houses.

This was agreed to.

Mr. JOHN BURNS moved the following new clause: "All regulations made under this Act shall be laid as soon as may be before Parliament, and the Rules Publications Act, 1893, shall apply to such regulations as if they were statutory rules within the meaning of Section 1 of that Act, and that Act as so applied shall, notwithstanding anything in Sub-section 5 of Section 1 thereof, extend to Scotland, with the substitution of a reference to the *Edinburgh Gazette* for the reference to the *London Gazette*."

The clause having been agreed to was embodied in the Bill which then passed through Committee.

FRIDAY, AUGUST 16TH.

Public Health (Regulations as to Food) Bill.

This Bill as amended was considered on report.

Mr. JOHN BURNS, when the report stage, which was formal, had been completed, appealed to the House to give the Bill a third reading. He repeated his assurance that the regulations under it would be drawn up by the Local Government Board with full consideration for all the legitimate interests concerned.

The Bill was then read a third time.

MONDAY, AUGUST 19TH.

The Medical Bureau at the Board of Education.

Sir PHILIP MAGNUS asked the President of the Board of Education whether, having regard to the fact that Clause 10 of the Education (Administrative Provisions) Act would enable local authorities to institute a system of periodical measurement of the children in attendance at public elementary schools, he would arrange, with a view to securing uniformity of method among local authorities desirous of availing themselves of the powers conferred by the Act, that instructions should be issued by the Board as to the best means of taking such measurements; and whether he would arrange that the data obtained should be duly tabulated at the offices of the medical bureau of the Board for information and reference.—Mr. MCKENNA answered: One of the duties to be undertaken by the Board of Education in connexion with Clause 10 of the Bill referred to, when it has become an Act, will be the careful collating, tabulating, summarising, and publishing of the most important results obtained from the medical inspection carried out by local authorities in the public elementary schools in their respective areas. I am considering in what way this duty may most effectively be carried out, but I think it would be highly inadvisable to make any decision in regard to it, until I have had the advantage of the medical advice which it will be necessary for the Board to become possessed of when the Bill has become law.

TUESDAY, AUGUST 20TH.

The Medical Officer at the Tokio Embassy.

Sir WILLIAM COLLINS asked the Secretary of State for Foreign Affairs whether the medical officer to the British Embassy at Tokio was a legally qualified medical practitioner in accordance with the requirements of the [illegible] Act, 1858.—Sir EDWARD GREY furnished the following written answer: I must remind the honourable Member that on June 4th last, in reply to a similar question, I informed him that I was not prepared to make any statement involving an interpretation of any part of the Medical Acts. I must adhere to what I then said.

The Mortality of Panama Labourers.

Mr. STAVELEY HILL asked the Under Secretary of State for the Colonies whether he would make inquiry into the rate of mortality among the labourers employed on the Panama Isthmian Canal.—Mr. CHURCHILL replied: I understand that the Secretary of State for Foreign Affairs has called for an official report but has not yet received it. I may mention, however, that very beneficial results have followed from the strict enforcement of sanitary laws and anti-mosquito regulations in the Canal zone and from the application of the new knowledge of tropical diseases to local conditions. In October, 1904, there were 21 deaths and 84 cases of yellow fever amongst 2706 non-immunes in a total of 19,243 men employed in the construction of the Canal. In October, 1905, among 4000 non-immunes in a total of 22,000 employees there was no death and only one case. This is an excellent instance of the inestimable value of the kind of research work which is being conducted by the Liverpool School of Tropical Medicine and other institutions of a similar kind.

The Plague Statistics.

Mr. REES asked the Secretary of State for India whether he would consider the advisability of giving, in Official Publications and Answers, together with the actual figures relating to plague mortality, the figures per mille of the population of India, in order that comparison might not be made with a population approximating to that of the United Kingdom.—Mr. MORLEY answered: I will bear in mind the honourable Member's suggestion in cases in which the additional information would be pertinent and correct and might prevent misleading comparisons. When, as frequently happens, plague is practically confined to a province, a per mille ratio to the population of India would itself be misleading.

WEDNESDAY, AUGUST 21ST.

Lead Poisoning in the China Trade.

Mr. ALDEN asked the Secretary of State for the Home Department whether he was aware that there were 12 cases of lead poisoning in the china and earthenware trade during last month; whether this was above or below the monthly average of such cases in this trade; and what steps he proposed to take with a view to diminishing the number of such cases.—Mr. GLADSTONE replied: It is the case, as stated in the question, that 12 cases of lead poisoning were reported to the Home Office in this industry in July. The number is above the average monthly number of cases during 1906 and the first six months of 1907; but, as my honourable friend will understand, the numbers fluctuate to some extent from month to month, and the total number of cases for the first seven months of this year is considerably below the number for the corresponding months in 1906—60 as compared with 63. The whole question of lead poisoning both in the potteries and in other trades is under my consideration.

BOOKS, ETC., RECEIVED.

BERGMANN, J. F., Wiesbaden. (F. BAUERMEISTER, 49, Gordon-street, Glasgow.)

Urologisch-Kystoskopisches Vademecum. Von Dr. Richard Wohlauer, Berlin, Ehem. Assistent der Klinik und Poliklinik von weiland Geh.-Rat Prof. Dr. Nitze. Price M.3.60 or 3*s.* 9*d.*

Price 30*s* net.

Lessons in Disinfection and Sterilisation. An Elementary Course of Bacteriology, together with a Scheme of Practical Experiments Illustrating the Subject-Matter. By F. W. Andrewes, M.A., M D. Oxon., F.R.C.P. Lond., D P.H. Cantab , Lecturer on Pathology, Pathologist, and Sanitary Officer to St. Bartholomew's Hospital, London. Second edition. Price 3*s.* 6*d.* net.

the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The fee is £5 for each examination. The subjects of the First Examination are: (1) Chemistry, Inorganic and Organic; (2) Biology (Zoology and Botany); and (3) Physics. The examination is divided into two parts—namely (1) chemistry and physics, and (2) biology; and candidates may pass in these parts separately. The subjects of the Second Examination are (*a*) Anatomy and Physiology (including Physiological Chemistry and Histology), and (*b*) Materia Medica and Pharmacy. Candidates may pass in *a* or *b* separately. The subjects for the Final Examination are (1) Pharmacology and Therapeutics; (2) General Pathology and Morbid Anatomy; (3) Forensic Medicine and Toxicology, and Public Health; (4) Obstetrics and Diseases of Women; (5) Surgery, Systematic, Clinical, and Practical; and (6) Medicine, Systematic, and Clinical, including Mental Diseases and Diseases of Children. Candidates may either present themselves in all the six subjects of examination on the same occasion, or may pass the examination in two parts, the first part consisting of two or three of subjects (1), (2), and (3); the second part of the remaining subjects. Candidates for the first part of the examination must have completed the fourth winter of medical study in accordance with the regulations of the University.

Degrees of Doctor of Medicine and Master of Surgery.—No candidate will be admitted to the degrees of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least one year has elapsed since he passed the examinations for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine: provided always that original work published in scientific journals or separately shall be admissible in lieu of, or in addition to, a dissertation specially written for the degree. No candidate shall be admitted to the degree unless his application after report from the Faculty of Medicine shall have been accepted by the Senate. Candidates may be required to undergo examination in any subject connected with the dissertation. The subjects of examination for the degree of Master of Surgery are (1) Surgical Anatomy, (2) Surgery, (3) Operative Surgery, (4) Clinical Surgery, (5) Ophthalmology, and (6) Pathology and Bacteriology.

Professors—Physiology: C. S. Sherrington, M.D., F.R.S. Physics: L. R. Wilberforce, M.A. Chemistry: J. Campbell Brown D.Sc. Natural History: W. A. Herdman, D.Sc., F.R.S. Botany: R. J. H. Gibson, M.A. Anatomy: A. Melville Paterson, M.D. Medicine: T. Robinson Glynn, M.D. Surgery: Rushton Parker, F.R.C.S. Pathology: Sir Rubert Boyce, M.B., F.R.S. Midwifery and Gynæcology: H. Briggs, M.D. Materia Medica and Therapeutics: W. Carter, M.D. Medical Jurisprudence: F. T. Paul, F.R.C.S. Hygiene: E. W. Hope, D.Sc. Tropical Medicine: Major Ronald Ross, C.B., F.R.S. Bio-Chemistry: D. Moore, D.Sc. Comparative Pathology: H. E. Annett M.D.

UNIVERSITY OF LEEDS.

Candidates presenting themselves for Matriculation in the Faculty of Medicine must pass an examination in English (Language or Literature) and English History, Mathematics and Latin, and in two of eight optional subjects. Exemption from the matriculation examination is granted to graduates of any university of the United Kingdom provided Latin has formed part of one of the degree examinations.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and a Diploma in Public Health.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and that they have attended courses of instruction approved by the University extending over not less than five years, two of such years, at least, having been passed in the University subsequently to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination.

The First Examination.—The First Examination consists of: Part I., Physics and Chemistry; Part II., Biology. Candidates will be allowed to pass the two parts separately.

The Second Examination.—The Second Examination consists of: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacy. Candidates will be allowed to pass the two parts separately.

The Final Examination.—The Final Examination consists of: Part I., Pathology and Bacteriology, Forensic Medicine, and Public Health. Part II., Medicine: Systematic and Clinical, including Mental Diseases and Diseases of Children; Surgery: Systematic, Clinical and Practical; Obstetrics and Gynæcology; Pharmacology and Therapeutics. Candidates will be allowed to pass the two parts separately and they may present themselves for examination in Part I. at the end of the twelfth term or fourth year of study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, to pass an examination. The dissertation, of which the subject must previously have received the approval of the Board of the Faculty of Medicine, must embody the results of personal observations or original research, either in some department of medicine or of some science directly related to medicine; provided always that original work published in scientific journals or in the Proceedings of learned societies, or separately, shall be admissible in lieu of, or in addition to, a dissertation specially written for the degree. Candidates will be required to write a short extempore essay on some topic connected with medicine and to answer questions on the history of medicine. They will also be examined orally on the dissertation or other work submitted. Any candidate may be exempted from a part or the whole of the examination if the Board of the Faculty so decide. No candidate will be admitted to the degree unless his application, after report from the Board of the Faculty of Medicine, shall have been accepted by the Senate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Every candidate is also required to furnish certificates of attendance in accordance with the regulations of the University. The subjects of examination are as follows: Surgical Anatomy, Surgery, Operative Surgery, Clinical Surgery, Ophthalmology, Pathology, and Bacteriology.

Diploma in Public Health.—The regulations for this diploma will be found on p. 656.

Professors—Physics: W. Stroud, D.Sc Chemistry: A. Smithells, B.Sc., F.R.S. Organic Chemistry: J. B Cohen, B.Sc. Zoology: W. Garstang, M.A. Botany: V. F. Blackman, M.A. Anatomy: T. Wardrop Griffith, M.D. Physiology and Histology: De Burgh Birch, M.D. Pathology: A. S. Grünbaum, M.D., F.R.C.P. Medicine: A. G. Barrs, M.D. Surgery: H. Littlewood, M.Sc., F.R.C.S. Obstetrics: (vacant). Public Health: J. S. Cameron, M.D. Forensic Medicine: H. J. Campbell, M.D.

UNIVERSITY OF SHEFFIELD.

Candidates for a medical degree shall have matriculated in the University or have passed such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board. The subjects required by the General Medical Council must be included in the Matriculation Examination or its recognised substitute.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

Degrees of Bachelor of Medicine

as had been done during the last 11 years in dealing with the regulations for the import of food and the shipping trade. With regard to the necessity for the regulations, he had been asked what would be done in the case of mineral waters. He would point out that in the East-end of London certain classes of mineral waters were made under such conditions that honourable Members, when they realised what these were, would agree that these waters should be brought within the scope of the Bill. The right honourable gentleman went on to refer to a case where the work of manufacture was carried on by a foreigner in Stepney in a yard beside a water-closet. The water was exposed to filthy contamination and some of the bottles had masses of matter in them that looked like mould. Several times last summer bottles filled on these premises had been returned by customers, and when Stepney people complained of bottles being dirty they were very dirty indeed. Frequently it happened that a person rented two rooms and started a mineral water factory. There was no machinery so that the place was not a workshop and it was not a factory. The sanitary conditions for the inmates might comply with the conditions of the local sanitary inspector but no other inspector had any power over premises of this kind. What the Local Government Board wanted to do was to supplement the powers of the local medical officer of health so that he might see that the conditions were not fraught with danger to the people engaged and to the consumers. He had been asked whether under this Bill it would be possible for a medical officer or an inspector to go into any kitchen. He would ask honourable members' attention as to the necessity of anyone going into a kitchen. In the district of what was supposed to be one of the best local authorities in the country there were restaurants where food was prepared for consumption and sale. In these the water-closet accommodation was reported to be in a defective condition and in 35 cases the water-closet communicated with the kitchen, and in some cases the water-closet was off the kitchen without ventilation. If the water-closet itself satisfied the sanitary inspector he had no power to prevent the preparation, storage, and distribution of food. They had, in London, districts where some of the choicest morsels and most expensive classes of food and drink were prepared in conditions which were absolutely intolerable and abominable. He had been asked what organisation was going to be resorted to for carrying out the regulations. The Local Government Board did not intend to create any new organisation. They did not intend to do anything in derogation of what any sanitary authority had the power to do. They intended to act through the existing medical officers and the local authorities for the purpose of enforcing these regulations. The local authorities with their existing staffs and their present expenditure would be able to do this work concurrently with much of their sanitary work. The Local Government Board did not intend to use these regulations as a means of harassing any trader or manufacturer in carrying on his business in a decent way. After the scandals which had been revealed in the last year or two the Board would not be doing its duty unless it sought for the powers contained in the Bill, and he asked honourable members to trust the Board in the regulations which were made under it. It was not intended that the Bill should apply to private houses.

Mr. GRETTON having withdrawn his amendment,

Mr. JOHN BURNS moved an amendment to make it clear that the Bill should not apply to ordinary private houses.

This was agreed to.

Mr. JOHN BURNS moved the following new clause: "All regulations made under this Act shall be laid as soon as may be before Parliament, and the Rules Publications Act, 1893, shall apply to such regulations as if they were statutory rules within the meaning of Section 1 of that Act, and that Act as so applied shall, notwithstanding anything in Sub-section 5 of Section 1 thereof, extend to Scotland, with the substitution of a reference to the *Edinburgh Gazette* for the reference to the *London Gazette*."

The clause having been agreed to was embodied in the Bill which then passed through Committee.

FRIDAY, AUGUST 16TH.

Public Health (Regulations as to Food) Bill.

This Bill as amended was considered on report.

Mr. JOHN BURNS, when the report stage, which was formal, had been completed, appealed to the House to give the Bill a third reading. He repeated his assurance that the regulations under it would be drawn up by the Local Government Board with full consideration for all the legitimate interests concerned.

The Bill was then read a third time.

MONDAY, AUGUST 19TH.

The Medical Bureau at the Board of Education.

Sir PHILIP MAGNUS asked the President of the Board of Education whether, having regard to the fact that Clause 10 of the Education (Administrative Provisions) Act would enable local authorities to institute a system of periodical measurement of the children in attendance at public elementary schools, he would arrange, with a view to securing uniformity of method among local authorities desirous of availing themselves of the powers conferred by the Act, that instructions should be issued by the Board as to the best means of taking such measurements; and whether he would arrange that the data obtained should be duly tabulated at the offices of the medical bureau of the Board for information and reference.—Mr. MCKENNA answered: One of the duties to be undertaken by the Board of Education in connexion with Clause 10 of the Bill referred to, when it has become an Act, will be the careful collating, tabulating, summarising, and publishing of the most important results obtained from the medical inspection carried out by local authorities in the public elementary schools in their respective areas. I am considering in what way this duty may most effectively be carried out, but I think it would be highly inadvisable to make any decision in regard to it, until I have had the advantage of the medical advice which it will be necessary for the Board to become possessed of when the Bill has become law.

TUESDAY, AUGUST 20TH.

The Medical Officer at the Tokio Embassy.

Sir WILLIAM COLLINS asked the Secretary of State for Foreign Affairs whether the medical officer to the British Embassy at Tokio was a legally qualified medical practitioner in accordance with the require-
cal Act, 1858.—Sir EDWARD GREY furnished the following written answer: I must remind the honourable Member that on June 4th last, in reply to a similar question, I informed him that I was not prepared to make any statement involving an interpretation of any part of the Medical Acts. I must adhere to what I then said.

The Mortality of Panama Labourers.

Mr. STAVELEY HILL asked the Under Secretary of State for the Colonies whether he would make inquiry into the rate of mortality among the labourers employed on the Panama Isthmian Canal.—Mr. CHURCHILL replied: I understand that the Secretary of State for Foreign Affairs has called for an official report but has not yet received it. I may mention, however, that very beneficial results have followed from the strict enforcement of sanitary laws and anti-mosquito regulations in the Canal zone and from the application of the new knowledge of tropical diseases to local conditions. In October, 1884, there were 21 deaths and 84 cases of yellow fever amongst 2705 non-immunes in a total of 19,243 men employed in the construction of the Canal. In October, 1905, among 4000 non-immunes in a total of 22,000 employees there was no death and only one case. This is an excellent instance of the inestimable value of the kind of research work which is being conducted by the Liverpool School of Tropical Medicine and other institutions of a similar kind.

The Plague Statistics.

Mr. REES asked the Secretary of State for India whether he would consider the advisability of giving, in Official Publications and Answers, together with the actual figures relating to plague mortality, the figures per mille of the population of India, in order that comparison might not be made with a population approximating to that of the United Kingdom.—Mr. MORLEY answered: I will bear in mind the honourable Member's suggestion in cases in which the additional information would be pertinent and correct and might prevent misleading comparisons. When, as frequently happens, plague is practically confined to a province, a per mille ratio to the population of India would itself be misleading.

WEDNESDAY, AUGUST 21ST.

Lead Poisoning in the China Trade.

Mr. ALDEN asked the Secretary of State for the Home Department whether he was aware that there were 12 cases of lead poisoning in the china and earthenware trade during last month; whether this was above or below the monthly average of such cases in this trade; and what steps he proposed to take with a view to diminishing the number of such cases.—Mr. GLADSTONE replied: It is the case, as stated in the question, that 12 cases of lead poisoning were reported to the Home Office in this industry in July. The number is above the average monthly number of cases during 1906 and the first six months of 1907; but, as my honourable friend will understand, the numbers fluctuate to some extent from month to month, and the total number of cases for the first seven months of this year is considerably below the number for the corresponding months in 1906—50 as compared with 63. The whole question of lead poisoning both in the potteries and in other trades is under my consideration.

Price 30*s* net.

Lessons in Disinfection and Sterilisation. An Elementary Course of Bacteriology, together with a Scheme of Practical Experiments illustrating the Subject-Matter. By F. W. Andrewes, M.A., M.D. Oxon., F.R.C.P. Lond., D.P.H. Cantab., Lecturer on Pathology, Pathologist, and Sanitary Officer to St. Bartholomew's Hospital, London. Second edition. Price 3*s*. 6*d*. net.

With respect to the places and institutions at which the studies of the candidate may be prosecuted, the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign university recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Of the subjects of study, 16 in number—viz., Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than eight must be taken in the University of Edinburgh or in some other university of the United Kingdom, or in some Foreign or Colonial university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court, or in a college incorporated with, or affiliated to, a university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court.

Women are admitted to graduation in medicine under practically the same conditions as men, excepting that, until provision is made in the University for instruction of women in all subjects of the medical curriculum, the regulations as to places of study contained in the foregoing paragraph do not apply to them. The Medical College for Women, 30, Chambers-street, Edinburgh, has been recognised as a medical school whose courses of instruction qualify for graduation.

Each candidate is examined, both in writing and orally, and clinically where the nature of the subject admits:—First, in Chemistry, Zoology, Botany, and Physics; second, in Anatomy and Physiology; third, in Materia Medica and Therapeutics and Pathology; and fourth, in Surgery, Medicine, Midwifery, Forensic Medicine, and Public Health, and clinically in Medicine, Surgery, and Gynæcology in a hospital. The examinations are conducted, as far as possible, by demonstrations of objects placed before the candidates. Candidates who profess themselves ready to submit to an examination in the first division of these subjects may be admitted to examination therein at the first period of examination after they have completed their attendance on the necessary classes. Candidates who have passed their examination in the first division of these subjects may be admitted to examination in the second division at the end of their third winter session. Candidates who have passed their examinations in the subjects comprised in the first and second divisions may be admitted to examination in the third division at the end of the fourth winter session. Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division when they have completed the fifth year of study.

Under a new medical ordinance it is provided that candidates may pass all or any of the subjects of the first division—viz., Botany, Zoology, Physics, or Chemistry—at a university in the United Kingdom or at any other university approved by the Senate for this purpose, when such subjects qualify for a degree in arts or science. In the second division the examination in Physiology may be taken at any time and in Anatomy at any time after the first half session of the third winter session. In the third division the examination in Pathology may be taken at any time after the end of the third summer session in the case of students who begin the medical curriculum in October and at the end of the fourth summer session in the case of students who begin their medical curriculum in May. In Materia Medica the examination may be taken at any time after the end of the fourth winter session. Candidates may be admitted to examination in Practical Pharmacy and in the physical, chemical, and botanical characters of medicinal substances at any examination held after they have completed the qualifying course of study. In the fourth division a student after taking the prescribed courses of study may be examined in Forensic Medicine and Public Health at any time, in Midwifery at any time after the end of the first half session, of the fifth winter session, in the Practice of Medicine and Surgery at any time after the end of the fifth winter session, and in Clinical Medicine (including the subject of Diseases Peculiar to Women) and Clinical Surgery at the end of the fifth year of study. These new ordinances apply to students who enter the University at or after the beginning of the winter session 1907, but students who have entered before this date have the option of finishing their course under the existing regulations or of taking advantage of the new ordinances.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £23 2*s.*, and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £6 6*s.*; for the Second Division (Anatomy, and Physiology) £5 5*s.*; for the Third Division (Pathology and Materia Medica and Therapeutics), £4 4*s.*; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, Clinical Gynæcology, and Forensic Medicine and Public Health), £7 7*s.*

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted for approval of the Faculty. The fee to be paid for the degree of M.D. is £10 10*s.*, and the fee to be paid for the degree of Ch.M. is £10 10*s.*

Professors—Natural Philosophy: J. G. Macgregor, D.Sc. Materia Medica: Sir Thomas R. Fraser, M.D., F.R.S. Forensic Medicine: H. Harvey Littlejohn, M.B., F.R.C.S.E. Chemistry: A. Crum Brown, M.D. Surgery: John Chiene, C.B., M.D. Medicine: J. Wyllie, M.D. Anatomy: D. J. Cunningham, M.D. Pathology: William Smith Greenfield, M.D. Midwifery: Sir John Halliday Croom, M.D. Clinical Medicine: Sir T. R. Fraser, W. S. Greenfield, and J. Wyllie. Clinical Surgery: T Annandale, M.D., F.R.C.S. Botany: I. Bayley Balfour, M.D. Physiology: E. A. Schäfer, M.D. Zoology: J. Cossar Ewart, M.D. Public Health, &c.: C. Hunter Stewart, M.B., D.Sc

---

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but eight of the subjects other than clinical must be taken in this or some other recognised university entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations six degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M.; B.Sc. in Public Health; D.Sc. in Public Health; and B.Sc. in Pharmacy. A Preliminary Examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, or French, or German, with possible options to students whose native language is not English in the case of the fourth subject. Candidates taking the University preliminary examination are not obliged to pass in all the four subjects at one examination but must do so at not more than two occasions.

For the degrees of M.B. and Ch.B. a curriculum of five years is required, in each of the first four of which the student must attend at least two five months' courses, or alternately one five months' course and two courses of two and a half months. The minimum of attendance in the first four years includes five months' courses in the following subjects:—Anatomy, Practical Anatomy (two courses), Chemistry, Materia Medica and Therapeutics, Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women and Infants, and Pathology; and courses of two and a half months in the following: Practical Chemistry, Physics, Botany, Zoology, Practical Physiology, Practical Pathology, Medical Jurisprudence, and Public Health. Candidates must attend at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted as clerk in medical and dresser in surgical wards, and he must must have had six months' out-door

Gloucester General Infirmary and Gloucestershire Eye Institution.—Assistant House Surgeoncy for six months. Salary at rate of £30 per annum, with board, residence, and washing.

Great Yarmouth Hospital.—House Surgeon, unmarried. Salary £90 per annum, with board, lodging, and washing.

Rimsby and District Hospital.—Resident House Surgeon. Salary £120 per annum, with board, lodging, and washing.

Emel Hempstead, West Herts Infirmary.—House Surgeon. Salary £100 per annum, with rooms, board, and washing.

Ull, Royal Infirmary.—Casualty House Surgeon. Salary £50, with board and lodging.

Icester Infirmary.—Assistant House Surgeon. Salary £50 per annum, with board, apartment, and washing.

Icester Isolation Hospital.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing.

Icester Poor-law Infirmary.—Resident Assistant Medical Officer. Salary £120 per annum, with rations apartments, and washing

Iverpool, Royal Southern Hospital.—Three House Physicians and Two House Surgeons. Salaries at rate of £60 per annum, with board and residence.

Ochgoilhead and Kilmorich Parishes.—Medical Officer. Salary £100 per annum.

Owestoft Hospital.—House Surgeon, unmarried, for six months. Salary at rate of £80 per annum, with board, lodgings, and washing

Oughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary £100 a year, with rooms, attendance, board, and washing.

Anchester, St Mary's Hospitals for Women and Children.—Third and Fourth House Surgeons for six months. Salary £25, with board and residence.

Anchester Children's Hospital.—Junior Resident Medical Officer, unmarried, for six months. Salary at rate of £80 a year, with board and lodging.

Anchester Royal Eye Hospital.—Junior House Surgeon. Salary £80, with residence, board, and washing.

Rkney, Parish of Rousay and Egilshay.—Resident Medical Officer. Salary £51 per annum.

Aisley, Riccartsbar Asylum.—Assistant Resident Medical Officer. Salary £100 per annum, with board and apartments.

T. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 a year, with board, lodging, and washing.

Carborough Hospital and Dispensary.—Senior House Surgeon. Salary £100 per annum, with residence and board.

Heffield Royal Hospital.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

Hrewsbury, Salop Infirmary.—House Physician. Salary at rate of £50 per annum, with board and apartments.

Tockport Infirmary.—Junior Assistant House Surgeon for six months. Salary £40 per annum, with board, washing, and residence.

Toke-on-Trent, North Staffordshire Infirmary and Eye Hospital, Hartshill.—Junior House Surgeon. Salary £50 per annum, with board, apartments, and washing.

Oxteth Park Workhouse and Infirmary.—Assistant Resident Medical Officer. Salary £100 per annum, with board, washing, and apartments.

Allasey Urban District Council.—Medical Officer of Health. Salary £500, increasing to £750.

Est End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, 73, Welbeck-street, W.—Honorary Registrar and Pathologist.

Est London Hospital, Hammersmith-road, W.—Two House Physicians and Three House Surgeons, tenable for six months.

Ork Dispensary.—Two Resident Medical Officers, unmarried. Salary £120 a year, with board, lodging, and attendance.

He Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Shere, in the county of Surrey.

Births, Marriages, and Deaths.

BIRTHS.

Cooke.—On August 15th, at Bournemouth, the wife of Francis H. Cooke, M.R.C.S., of a son.

Wales.—On August 14th, at Mevell Hall, Gargrave in Craven, the wife of Herbert Wales, M.A., M.B., B.C., *of a son.*

MARRIAGES.

Forrester—Hartnoll.—On August 14th, at St. John's, Potters Bar, Charles Carmichael Forrester M.D., to Adeline Braund, youngest daughter of the late James Hartnoll of Ganwic, Barnet.

Norman—Harrison.—On August 7th, at the Parish Church, Holton St. Mary, Suffolk, J. Clement A. Norman, M.R.C.S., L.R.C.P., to Maud Welfitt, eldest daughter of George Tonkin Harrison, of The Hall, Holton St. Mary, Suffolk.

DEATH.

Brown.—On August 12th, aged 50 years, Walter Henry Brown, M.Sc. Leeds, F.R.C.S.I., M.R.C.S. Eng., of Highfield House, Headingley, Leeds, Consulting Surgeon, Leeds General Infirmary.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE USE AND ABUSE OF ALCOHOL.

In The Lancet of March 30th, 1907, we published a pronouncement with reference to the use of alcohol signed by a group of representative medical men. We have been receiving from America lately by post after post photographic reproductions of this article, which appear to have been disseminated widely in the States by a body called the National Wholesale Liquor Dealers' Association of America. We are powerless to stop this proceeding and must submit also to the further misrepresentation, which is quite sure to be made, that we are in league with the National Wholesale Liquor Dealers' Association of America. Our position in regard to this important pronouncement is exactly defined by an introductory paragraph appearing in our columns simultaneously, and we are constrained to believe that the assertions attributing to us an interest in publishing the document far and wide are made with knowledge of their incorrectness.

HERBALIST HUMBUGS.

A non-medical correspondent, writing in a recent issue of the *Sheffield Daily Telegraph*, holds up to proper reprobation the preposterous pretensions of herbalising quacks to an exclusive knowledge of the medicinal properties of vegetable remedies. He takes for his text a pamphlet which he has received from a herbalist company trading under the title of "doctor," from which he quotes rubbish of the following nature: "The medical profession despise herbs, and use dangerous minerals and poisons instead, to the great injury of their patient." Further extracts from this pamphlet assert that "milk is grass in a liquid condition," whilst we read that the flesh of the cow is "solid extract of herbage." The correspondent dilates at some length on the flourishing condition of modern quackery which is undoubtedly largely fostered by the broadcast distribution of this sort of lying pamphlet. We have frequently given expression to such words as those with which he concludes his letter: "The charlatan's only qualification is that he can produce a badly written pamphlet based upon a diseased notion of what medicine ought to be. That the State should permit the wholesale deception is a scandal, nay, it is a tragedy." A large part of the letter is occupied in a statement of the prior claims of the medical profession to treat disease, which many people may read with advantage, but this champion of the profession would not have weakened his cause if he had omitted to write: "There is not a single herb in the world of any value unknown to medical and pharmaceutical science." This is a somewhat too universal negative for ready acceptance. We entirely agree, however, with the remark that "the average herbalist's method of extracting the medicinal virtues from an herb are crude, unscientific, and very unreliable."

HEALTH AND HOSPITALS IN GIBRALTAR.

A report on the Blue-Book of Gibraltar for the year 1906 has been prepared by Mr. Frederick Evans, colonial secretary of the colony, and presented by command of His Majesty to both Houses of Parliament. The report states *inter alia* that the sanitary condition of Gibraltar is steadily improving. The death-rate, which in 1935 was 18·17 per 1000 of the estimated population (25,140), compares very favourably with that of the crowded towns of England and Wales. The epidemic of small-pox which commenced in October, 1905, proved to be one of the severest on record. Special measures were adopted to cope with it and all possible precautions were taken to prevent the disease being spread. When the east wind, or "Levanter," prevails during the summer months a heavy cloud hangs over the rock and the sheltered position of the town at the base of the western side of the rock makes the heat very oppressive; otherwise the sub-tropical climate is an agreeable one to reside in. The temperature is highest in the months of June, July, August, and September. The prevailing wind is easterly, although it frequently blows with considerable force in the winter months from the south west and north-west. The mean temperature for the year was 65·1° F. Statistics taken over a period of 115 years show the average annual rainfall to be 33·33 inches. A hospital for the treatment of the sick was first established at Gibraltar in 1815, when an old building known as the "Blue Barracks" was repaired at Government expense and handed over to the public for use as a civil hospital. It was maintained by public subscriptions, assisted by an annual grant from the Government and by the contributions of paying patients. A tax was also levied on flour in aid of the hospital funds. Every vessel anchoring in the bay was required to pay 3s. 3d. Lighters, ferry-boats, &c., paid 4s. 4d. annually. In 1880 the foundation-stone of a new hospital on the same site was laid by the Governor, General Lord Napier of Magdala. The building was completed in 1888 at a cost of £24,000, which was met from Government funds. The building consists of several separate blocks, each block having been brought into use as completed. Until 1885 the hospital was divided into separate divisions: Protestant, Roman Catholic, and Hebrew. Each was under separate management, there being a deputy governor of each persuasion. In that year an Ordinance was passed under which a

Preliminary Examination. *The Preliminary Examination* for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the *required subjects*). Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of L.L.A.

Degree of Bachelor of Medicine and Bachelor of Surgery.—Candidates must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. *Additional subjects* of study are Practical Pharmacy, Mental Diseases, Practical Midwifery (12 cases of labour), Vaccination, Children's Diseases, Fevers, Ophthalmology, and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court.

Women shall be admitted to gradnation in Medicine, subject to the provisions of Ordinance No. 18 [General No. 9—Regulations for the Graduation of Women and for their *Instruction in the Universities*]; Provided always that every candidate for graduation shall produce evidence of having satisfied the conditions herein laid down with respect to the Preliminary Examination, and shall be examined in all the subjects necessary for graduation by the Examiners of the University of St. Andrews. All the classes necessary for graduation shall be taken in the University of St. Andrews, except in so far as instruction obtained elsewhere is allowed by the said Ordinance.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate shall be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy, Physiology, and Materia Medica; third, in Pathology, and Forensic Medicine and Public Health; and fourth, in Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 10 guineas, exclusive of any stamp duty which for the time may be demanded. The fee to be paid for the degree of Master of Surgery shall be 10 guineas.

The whole medical curriculum can be taken in University College or the first two years in United College.

Bursaries, United College, St. Andrews.—Fourteen Taylour Thomson Bursaries for female Medical students of the annual value of from £20 to £30 each, tenable for one or two years. The Bursaries are awarded in the order of merit, the most valuable ones being given to those students who obtain the highest marks in the Preliminary Examination and who are prepared to take two Anni Medici at the United College, St. Andrews.

University College, Dundee.—(*a*) Open to either sex. Eleven Entrance Bursaries of £15, tenable for one year. (*b*) *Open to either sex: Four £20* and three £15, second year. (*c*) Four £20 and two £15, third year. (*d*) Bute Bursary, founded in 1893 by the late Most Honourable the Marquis of Bute, K.T. This Bursary consists of the free proceeds of £1000. (*e*) Two Bursaries of the annual value of £25, tenable for three years at either University College, Dundee, or at any Scottish University (local candidates only).

Professors—Natural Philosophy: J. P. Kuenen, Ph.D. Chemistry: James Walker, D.Sc. Natural History: D'Arcy W. Thompson, B.A. Botany (White's): Patrick Geddes, F.R.S.E. Anatomy (Cox's): J. Yule Mackay, LL.D. Physiology: E. W. Reid, B.A. Pathology: L. R. Sutherland, M.B., C.M. Surgery D. Macewan, M.D. Medicine: Alexander M. Stalker, M.D. Midwifery: J. A. C. Kynoch, M.B., F.R C.P. Edin. Materia Medica: C. A. Marshall, M.D.

United College of St. Salvator and St. Leonard.—Professors—Natural Philosophy: A. S. Butler, M.A. Natural History: W C MacIntosh, M.D., LL.D., F.R.S Medicine: J. Bell-Pettigrew, M.D., LL.D., F.R.S. Chemistry: Thomas Purdie, B.Sc., Ph D, LL D., F.R.S. Anatomy: James Musgrove, M.D., C.M.

For further particulars apply to the Dean of the Medical Faculty, University College, Dundee.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must pass a matriculation examination, for which a fee of 5*s.* is payable. No student can be admitted for the winter course after Nov. 25th.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be concurrent with the medical course and the B.A. degree need not be taken before the final medical examinations, but the medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Systematic, Practical and Applied Anatomy, Chemistry and Practical Chemistry, Surgery and Operative Surgery, Histology, Botany, Zoology, Physics, Physiology and Practical Physiology, Practice of Medicine, Midwifery, Pathology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Dublin Hospital (one year at a recognised London or Edinburgh hospital before the commencement of the Dublin curriculum may be counted as one year spent in such Dublin hospital); (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 30 cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany and Zoology. The Intermediate Medical Part I., including Anatomy and Institutes of Medicine (Practical Histology and Physiology). The Intermediate Medical Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica, Jurisprudence, and Pathology; and Part II., Medicine, Surgery, Midwifery, Gynæcology, Clinical Medicine, Mental Diseases, Clinical Surgery, Operations, and Clinical Ophthalmology. Part I. may be passed in the fourth year and Part II. in the fifth year. Fee for the *Liceat ad Examinandum*, £10. Fee for the degrees, £17.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He mus[illegible] read a thesis before the Regius Professor of Physic. this degree, £13.

George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1907, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch" should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Daily Express, Morning Advertiser, Broad Arrow, Pall Mall Gazette, Hackney Mercury, Plymouth Morning News, Kensington News, Chiswick Times, Essex Times, Hertfordshire Standard, Essex Newsman, Gresham Standard, Oxford Chronicle, Glasgow Weekly Herald, Wellingborough News, Oxford Gazette, Leamington Spa Courier, Midland Evening News, Norwich Press, &c.*

University College, Cardiff: School of Medicine.—All classes are open to both men and women students who may spend three out of their five years of medical study at Cardiff. The courses of study are recognised as qualifying for the Preliminary Scientific and Intermediate Examination in Medicine in the University of London and for the corresponding examinations in the other Universities. Students who are preparing for these examinations may compound for their courses by paying a fee of £57 10*s.*, while a composition fee of £41 10*s.* includes all the necessary courses for the first and second examinations for the Diploma of the Conjoint Board. In all cases the composition fees may be paid by instalments. Hospital instruction is given at the Cardiff Infirmary. The attention of students about to matriculate is drawn to the numerous entrance scholarships and exhibitions, varying in value from £10 to £30 per annum, offered for competition at University College, Cardiff, in September next, most of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registrar. In the department of Public Health established in 1899 instruction is given qualifying for the D.P.H. examinations. Further information may be obtained from the Dean of the Faculty of Medicine.

Lecturers.—Physics: Professor A. L. Selby. Chemistry: Professor C. M. Thompson. Zoology: Professor W. N. Parker. Botany: Professor A. H. Trow. Anatomy: Professor David Hepburn. Physiology: Professor J. B. Haycraft. Materia Medica and Therapeutics: Dr. W. Mitchell Stevens. Bacteriology: Mr. H. A. Schölberg. Public Health and Hygiene: Dr. E. Walford and Dr. W. Williams. Midwifery: Dr. E. J. Maclean. Vaccination: Mr. H. A. Schölberg.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.[2]

Any candidate who desires to obtain both the Licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to complete five years of professional study at recognised Medical Schools and Hospitals and to comply with the following regulations and to pass the examinations hereinafter set forth. Six months of the curriculum may be spent in an Institution recognised by the Board for instruction in Chemistry, Physics, Practical Chemistry, and Biology.

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to Mr. F. G. Hallett, secretary of the Examining Board, Examination Hall, Victoria Embankment, W.C., 14 clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the *First Examination* are—Chemistry, Physics, Elementary Biology, and Practical Pharmacy. A candidate may take this examination in three parts at different times (Chemistry and Physics must be taken together until the required standard is reached in both or in one of these subjects, but a candidate will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other). A candidate will be admitted to examination in Chemistry and Physics, in Practical Pharmacy, and Elementary Biology on producing evidence of having passed the required Preliminary Examination and of having received instruction in these subjects at a recognised institution, or he may take Pharmacy at any time during the curriculum. (*Note:* In the case of students who commence their professional studies after June 1st, 1904, certificates must be produced of 180 hours' instruction and laboratory work in chemistry; 120 hours' instruction and laboratory work in physics; and 120 hours' instruction and laboratory work in biology. These courses need not be completed within one year, nor need they run concurrently, and they may be commenced or attended before the candidate passes the required preliminary examination in general education.) Synopses of the subjects of examination may be obtained on application. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry, Physics, or Biology he must produce evidence of further instruction at a recognised Institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine on any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects in which he has passed.

The fees for admission to the *First Examination* are as follows: For the whole examination, £10 10*s.*; for re-examination after rejection in Parts I. and II., £3 3*s.*; and for re-examination in each of the other parts, £2 2*s.*

The subjects of the *Second Examination* are Anatomy and Physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the Second Examination on production of the required certificates of professional study. The study of Anatomy and Physiology before passing in two of first three parts of the First Professional Examination is not recognised.

A candidate referred on the *Second Examination* will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his Anatomical and Physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the *Second Examination* are: £10 10*s.* for the whole examination and £6 6*s.* for re-examination after rejection.

The subjects of the *Third* or *Final Examination* are: Part I. Medicine, including Medical Anatomy, Pathology, Practical Pharmacy, Therapeutics, Forensic Medicine, and Public Health. Candidates who have passed in Practical Pharmacy at the First Examination will not be re-examined in that subject at the Third Examination. Part II. Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances. Part III. Midwifery and Diseases Peculiar to Women. Candidates may present themselves for examination in Midwifery and Diseases of Women at any time after the completion of the fourth year of professional study at a Medical School and Hospital, not less than one year after passing the Second Examination, on production of the required certificates. Candidates may present themselves for examination in Medicine and Surgery at the completion of the five years' curriculum, not less than two years from the date of passing the Second Examination, on production of the required certificates. Candidates may take this examination in three parts at different times, or they may present themselves for the whole examination at one time. They will be required to produce the following evidence before being admitted to the several parts of the *Third* or *Final Examination*—viz., in Medicine, of having attended Lectures on Medicine, Pathology including Bacteriology, Pharmacology, and Therapeutics, Forensic Medicine, and Public Health; Practical Instruction in Medicine; Medical Hospital Practice during two winter and two summer sessions; Demonstrations in the Post-mortem Room during 12 months; Clinical Lectures on Medicine during nine months; of having discharged the duties of Medical Clinical Clerk; Instruction in the Administration of Anæsthetics; Practice of a Fever Hospital and Clinical Demonstrations at a recognised Lunatic Asylum; in Surgery, of having attended Lectures on Surgery and Pathology including Bacteriology; Practical Instruction in Surgery; of having performed operations upon the Dead Subject; Surgical Hospital Practice during two winter and two summer sessions; Demonstrations in the Post-mortem Room during 12 months; Clinical Lectures on Surgery during nine months; of having discharged the duties of Surgical Dresser; Instruction in the Administration of Anæsthetics; and Clinical Instruction in Ophthalmology; in Midwifery

---

[2] The diploma of Member of the Royal College of Surgeons of England and the Licence of the Royal College of Physicians of London are no longer granted separately except to students who commenced their professional study prior to Oct. 1st, 1884.

THE LANCET.

LONDON: SATURDAY, AUGUST 31, 1907.

An Address to Students.

In the early days of October words of welcome and of warning will be addressed in a certain number of medical schools to the students entering upon the medical educational curriculum. The official introductory lecture is not now, as it was by former generations, considered to be an essential feature of the beginning of the winter session in every medical school. Nevertheless, either in the old-established manner, or through the pages of its hospital journal, or in the speeches at the inaugural dinner, or in some other formal or informal manner, each institution engaged in medical education endeavours to bring home to its new students the importance of the step they are taking in seeking entrance to the medical profession. These individual sectional congratulations will necessarily to a large extent be occupied in pointing out the advantages of the particular university or medical school to which the fortunate student has attached himself, and in endeavouring to sow the seeds of the institutional *esprit de corps* which is such an important element of medical as of all other forms of education.

A Word of Welcome.

The Lancet—and when we speak for ourselves we speak for our readers—regards the annual festival of the induction of novices from a somewhat wider standpoint than that naturally taken by the introductory lecturer attached to one of the seats of medical learning. The five or six probationary years spent in what is technically regarded as the educational period cannot be clearly defined from that long period of study which *does not cease* till the medical man retires altogether from the practice of his profession. Once a medical student always a medical student, and our congratulations are offered not so much to the recruit as he enters upon his five years of more or less irresponsible institutional life as to the budding professional man seeking the perpetual service of two hard masters—science and the public. We most heartily and unreservedly, then, congratulate all those men who have decided on October 1st, 1907, to put their hand to the plough. There is only one class of man who must be exempted from such congratulations—he who, looking round for an occupation in life in which to make money easily has chosen the medical profession: with him we must condole, for he has mistaken his path. To all others, whether they be attracted by a love of science, by the possession of mechanical aptitude, by a desire for service to the afflicted, or merely by a wish to follow in the footsteps of a father or some other hero of their youth, our welcome is cordial and confident. To all such an assurance may be given that hard as a medical man's life may be in particular instances, in the great majority of cases the good features undoubtedly predominate over the evil. That there are a large number of thoroughly unsatisfactory features in many branches of practice none can doubt. Those who would minimise the defects in the organisation of the medical profession which prevent it from fulfilling its work with complete satisfaction, either to the public or to its own members, would do an ill-service to the recruits about to enter its ranks. To conceal these defects can only lead to disillusion when the student passes from the hospital to the full work of his profession. To bring them before him in his early days may secure that he will be prepared to take his share in minimising or removing them whenever opportunity arises. The existing defects, both in medical education and in the practice of medicine, are of a class that is amenable to treatment. They need deter none from joyfully and hopefully entering our ranks. Whilst the founder of The Lancet was exposing in his vigorous manner the glaring evils of the profession of his time there appeared year by year in this journal an address of welcome to new students. To Wakley, keen reformer as he was, we doubt not that the existence of abuses to be battled with and overthrown seemed an added attraction to those entering the profession. We take a less combative line and do not set forth the need of medical reform as a bait to intending students, but we confidently ask the attention of all those who are joining us to some aspects in which the education for the practise of our profession falls short of the ideal, in order that being forewarned they may be forearmed, and so may secure for themselves and for their future patients the best that is possible under existing conditions.

The Value of Medical Training.

In urging each new colleague to try to escape the pitfalls that beset him during his official educational curriculum we appeal direct to his self-interest. The avoidance of evils that abound in his subsequent professional practice will later require the exercise of a considerable amount of altruism. It is fortunate, therefore, that the student's life in a medical school is well calculated to develop a true spirit of unselfishness. In fact, as a school of character it is doubtful if any better could be devised than the routine career of a medical student. It is not claimed that every medical student at the end of his five years' curriculum will be found to have become a saint. But if he has not developed manly qualities of self-restraint, courage, gentleness, and forbearance it is not for want of opportunity of practising these virtues. To every youth entering on his probationary training for manhood there are opportunities, whatever calling he has chosen, of showing the stuff that he is made of and of putting into practice the precepts he has learnt from his teachers, and especially from those candid friends his school fellows. During the earlier period of a medical student's career the conditions do not differ much from those of all other boys on leaving their schools of general education. The medical student's temptations may be rather greater in so far as supervision by authority over medical students is in most instances less than in the case of youths passing into office work in connexion with commerce or other branches of activity. But it must be remembered that many medical students are not youths at all, while the interest of the work is incomparably

instruction: Physics, three *months*; *Elementary Biology*, three months; Chemistry, six months; Practical or Analytical Chemistry, three months; *Anatomy*, during at least six months; Practical Anatomy, twelve *months*; Physiology, six months; Materia Medica, *three* months; Pathology (including *Practical Pathology*), six months; Practice of Medicine, six months; *Clinical Medicine*, nine months; *Principles* and Practice of Surgery, *six months*; *Clinical* Surgery, nine *months*; Midwifery and the *Diseases* of Women and Children, three months; Medical Jurisprudence and Public Health, three months. The number of lectures certified as attended at any school not situated in Scotland should not be less than three-fourths of the total number of lectures delivered in a course. 2. The candidate must also produce the following certificates:—(*a*) Of having personally attended not less *than six* cases of labour, or alternatively attendance on 12 cases of labour, at least five of these to be conducted personally under the direct superintendence of the practitioner who signs the certificate, *who must be a registered* medical practitioner. (*b*) Of having attended, for three months, instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of *Practical Pharmacy*. (*c*) *Of having attended* for 27 *months* the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing *distinct staffs of* physicians and of surgeons. Evidence must be produced that the candidate has acted as Surgical Dresser and Medical Clinical Clerk for not less than three months in the wards in each case. (*d*) Of having attended for six months the practice of a public dispensary specially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital or of having acted for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second examinations. (*e*) Of having been instructed in the Theory and Practice of Vaccination by a Public Vaccinator authorised by the Local Government Board to grant certificates of proficiency in vaccination and of having performed operations under the teacher's inspection during a period of not less than six weeks.

In addition to the courses above prescribed candidates are required to attend the following courses: Diseases and Injuries of the Eye, three months; *Insanity*, *three months*; Infectious Diseases, three months.

The curriculum lasts for five years; the *fifth* year should be devoted to clinical work at one or more public hospitals or dispensaries. The period of three years devoted to hospital practice may include clinical instruction in special subjects, and should also include instruction in administration of anæsthetics and attendance at post-mortem examinations. The student's regularity of attendance in the wards and out-patients' departments of the hospitals and at the post-mortem examinations should be duly ascertained and noted on the certificate.

Candidates shall be subjected to four professional examinations:

First Examination.—The First examination shall embrace the following divisions of subjects—(1) Physics, (2) Chemistry, *including* Practical Chemistry, and (3) Elementary Biology. The fees payable for admission to the *First* examination shall be for the whole examination, £5; for each division separately, £2 10*s*.

Second Examination.—The Second examination shall embrace Anatomy and Physiology including Histology; and candidates may be admitted to this examination at the end of the second year of *medical study*. *The* fees payable for admission to the Second *examination* shall be—for the whole examination, £5, and for re-entry after rejection, £3 for both subjects, and £2 if one of the subjects has been passed.

Third Examination.—The Third examination shall embrace Pathology and Materia Medica with Pharmacy. The fees payable for admission *to* the Third examination shall be—for the whole examination, £5; for re-entry in both subjects after rejection, £3; and £2 if one of the subjects has been passed.

Final Examination.—The Final examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, *including Therapeutics*, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and *Diseases and Injuries of the* Eye; Midwifery and *Diseases of* Women and of New-born Children; and Medical Jurisprudence *and* Public Health. All candidates shall be subjected, in addition to the written and oral examinations, to clinical *examinations* in Medicine and Surgery, *which shall* include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope Examination of *the Urine and Urinary Deposits*, *Surgical* Appliances, Bandages, Surface *markings*, &c. The fees *payable* for the Final *examination* shall be,—for the whole examination, £15, for re-entry in all subjects after rejection, £5.

Candidates who enter on the footing of having passed the earlier examination at another Board shall pay the fees in respect of these examinations, as well as the Final examination fees.

There are six periods of examination annually, four in Edinburgh and two in Glasgow, and candidates may present themselves at either examining centre irrespectively of the place of the previous examination. The *Registrar* in Edinburgh is Mr. J. Robertson, solicitor, 54, George-square; and the *Registrar* in Glasgow, Mr. A. Duncan, LL.D., 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations.

Note.—In applying for copies of the Regulations students should state whether they commenced medical study before or after Jan. 1st, 1892, a warning which it is to be hoped has no *longer much* application.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

In addition to the diplomas granted by the Scottish Conjoint *Board* the Royal College of Physicians and the Royal *College* of Surgeons of Edinburgh grant honour diplomas which no longer give the right to practise professionally if *held separately*, and also grant their Single Licence *to* candidates already possessing legal qualifications for *professional* practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship*.

Membership.—A candidate, who must be a Licentiate of the College of Physicians or a graduate of a British or Irish University and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine, such as general pathology, psychology, public health, obstetrics, tropical medicine, or medical jurisprudence. A candidate who for 40 years has been in the practise of his profession may be excused any or all of the examination. The fee for the Membership is £36 15*s*., 15 guineas of which will be returned to any successful candidate who was already a Licentiate of the College at the time of qualifying for the Membership.

Fellowship.—The Fellows are selected, save with rare exceptions, from the ranks of the *Members*. They must be 25 years of age. The fee is £64 18*s*.

The College grants its *Single Licence* on terms similar to those of the Royal College of Surgeons of Edinburgh, as mentioned in the next section.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The Royal College *of Surgeons* of Edinburgh grants a diploma *of Fellowship* after *examination* to the *holders of* the surgical degrees of diplomas of the recognised *British* examining bodies, as well as of the holders of *the surgical* degrees of the Universities of Canada, *Australia*, New Zealand, and the Indian Empire. The candidates for the examination must be 25 years of age and *must* have been engaged in practice for at least two years. The examination is of a practical nature, partly written and partly *viva voce*, and includes surgery and surgical anatomy, *operative* surgery, and clinical practice. One optional *subject* can also be taken, the range of these *specialisms covering* every branch of medicine. The fee to be *paid on* obtaining Fellowship is £45, £15 of which will be returned to those who already hold the Licentiateship of the College. *Three weeks'* most insatiable inquisitiveness. If the medical student's desire to know has not been already hampered by school methods he will have placed before him in crescendo scale subjects of study which none but the most *blasé* appetite could regard with indifference. The only possible difficulty is that the second and third courses are so inviting that there is fear that the earlier fare may suffer by comparison with those that come after—may be bolted and not digested.

THE OVERCROWDING OF THE STUDENT'S TIME.

Medical students are sometimes consoled by their teachers for the inevitable delay in reaching the study of disease and in coming into contact with patients by a consideration of the usefulness of their early studies in enabling them to understand the later. There would not be the same necessity to plead utility if the prevalent system of examinations would allow the teachers of the ancillary sciences to present their subjects in their most interesting guise unhampered by scheduled courses of instruction and syllabuses for the guidance of external examiners. We do not propose to discuss the possibility of altering this state of things at the present moment, for that would be waste of time, but there is no reason why the student should not know what a casual perusal of recent proceeding at the meetings of the General Medical Council will reveal, that the medical curriculum is overcrowded and that the percentage of failures in examinations is quite unduly high when the industry of the pupils and the zeal of their teachers are taken into account. At the present time, while it is possible for an intelligent and industrious student, aided by a thoughtful teacher, to escape some of the difficulties of a multitude of examinations in a too rigid curriculum, it is not so easy to avoid the trouble due to the excessive number of subjects to be dealt with. This overcrowding is especially noticeable in the latter part of his course, and is due to the fact that the State requires every medical man to be prepared to cope with a vast number of different emergencies. After he is qualified he may, and almost must, decide to restrict his practice to certain branches of professional work, but at the outset he is expected to show at least an elementary acquaintance with every professional department. It is only by the exercise of method and industry in a very high degree that it is possible for a medical student to acquire this elementary knowledge of all his subjects without running a risk that his acquaintance with each is superficial as well as elementary, while unfortunately the superficial acquaintance may suffice for the purposes of an examination even more aptly than deeper knowledge. It is essential that from the very commencement of his studies a student should work not only in the right spirit but with great industry and perseverance. He must look ahead and plan out his leisure time as well as his working hours if he is to pass his examinations in due sequence and also master the ground-work of his professional studies.

He must select forms of physical recreation which can be fitted in with the exacting duties in the medical school and will yet be sufficient to maintain a high standard of bodily health. Indifferent health will be a serious bar to the practice of medicine, and may prevent the satisfactory completion of the course of study necessary in order to secure legal qualifications. Physical exercise should be both a means of securing health and also of providing recreation and social intercourse. If it can secure social intercourse with non-medical students so much the better. Medical education is very engrossing and there is a material risk that a student's outlook may be narrowed despite, or because, of the plethora of subjects with which he has to make himself more or less familiar. He will need, when qualified, to have the widest possible knowledge of mankind and sympathy with the point of view of all classes. It is, therefore, well that a student, while not neglecting the social, literary, and sporting clubs of his own medical school, should take every opportunity of mixing with students in all other faculties of his university if he fortunately belongs to one. It is the ease with which such intercourse is obtained in the old universities that makes Oxford and Cambridge so valuable as places in which to pursue the earlier medical studies, while it is one of the set-backs to the success of the University of London that such intercourse is not yet systematically promoted. It should not, however, be impossible to secure the broadening influence of social intercourse in any city in which medical education is carried on, and it will be observed that all the provincial Scottish and Irish universities are located in or in the vicinity of comparatively large cities. The moral of our words of welcome and of warning, so far as the educational curriculum is concerned, is that its splendid opportunities and results may well be missed by the man who lets himself slide in the direction of least resistance, but will certainly be secured in more or less full measure by anyone who recognises the dangers and difficulties and sets out with the fixed purpose of making the five years of medical study the most profitable as well as the happiest years of his life.

THE PROFESSIONAL OUTLOOK.

It is an inevitable disadvantage of the disappearance of the old apprenticeship system from medical education that only a small proportion of our modern students when first entering upon their work have a conception of what we may call the ideals of the profession. In a former generation the majority of general practitioners implanted in their pupils the professional spirit without which the highest scientific training must certainly fail in producing the right sort of medical practitioner. To-day this professional spirit must be evolved by other means if the profession is to maintain its noble traditions. If there is rather a loud outcry that these traditions are in special danger just now, we venture to hope that this is due to the excessive introspection and publicity of our time rather than to any real lowering of the high aim of the majority of the profession. This high aim is distinctly an unselfish one and must be kept constantly before each of us from the first moment of entrance into the ranks of medicine. It must be encouraged on all hands by precept and by example. Some believe that this high aim can even be compelled, to a certain extent, by regulations imposed by professional organisation. But a nation cannot be made sober by Act of Parliament, nor can a profession be inspired with lofty ideals by by-laws and codes of ethical rules. Yet

instruction: Physics, three months; Elementary Biology, three months; Chemistry, six months; Practical or Analytical Chemistry, three months; Anatomy, during at least six months; Practical Anatomy, twelve months; Physiology, six months; Materia Medica, three months; Pathology (including Practical Pathology), six months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery and the Diseases of Women and Children, three months; Medical Jurisprudence and Public Health, three months. The number of lectures certified as attended at any school not situated in Scotland should not be less than three-fourths of the total number of lectures delivered in a course. 2. The candidate must also produce the following certificates:—(*a*) Of having personally attended not less than six cases of labour, or alternatively attendance on 12 cases of labour, at least five of these to be conducted personally under the direct superintendence of the practitioner who signs the certificate, who must be a registered medical practitioner. (*b*) Of having attended, for three months, instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy. (*c*) Of having attended for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. Evidence must be produced that the candidate has acted as Surgical Dresser and Medical Clinical Clerk for not less than three months in the wards in each case. (*d*) Of having attended for six months the practice of a public dispensary specially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital or of having acted for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second examinations. (*e*) Of having been instructed in the Theory and Practice of Vaccination by a Public Vaccinator authorised by the Local Government Board to grant certificates of proficiency in vaccination and of having performed operations under the teacher's inspection during a period of not less than six weeks.

In addition to the courses above prescribed candidates are required to attend the following courses: Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months.

The curriculum lasts for five years; the fifth year should be devoted to clinical work at one or more public hospitals or dispensaries. The period of three years devoted to hospital practice may include clinical instruction in special subjects, and should also include instruction in administration of anæsthetics and attendance at post-mortem examinations. The student's regularity of attendance in the wards and out-patients' departments of the hospitals and at the post-mortem examinations should be duly ascertained and noted on the certificate.

Candidates shall be subjected to four professional examinations:

First Examination.—The First examination shall embrace the following divisions of subjects—(1) Physics, (2) Chemistry, including Practical Chemistry, and (3) Elementary Biology. The fees payable for admission to the First examination shall be for the whole examination, £5; for each division separately, £2 10*s*.

Second Examination.—The Second examination shall embrace Anatomy and Physiology including Histology; and candidates may be admitted to this examination at the end of the second year of medical study. The fees payable for admission to the Second examination shall be—for the whole examination, £5, and for re-entry after rejection, £3 for both subjects, and £2 if one of the subjects has been passed.

Third Examination.—The Third examination shall embrace Pathology and Materia Medica with Pharmacy. The fees payable for admission to the Third examination shall be—for the whole examination, £5; for re-entry in both subjects after rejection, £3; and £2 if one of the subjects has been passed.

Final Examination.—The Final examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women and of New-born Children; and Medical Jurisprudence and Public Health. All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface markings, &c. The fees payable for the Final examination shall be,—for the whole examination, £15, for re-entry in all subjects after rejection, £5.

Candidates who enter on the footing of having passed the earlier examination at another Board shall pay the fees in respect of these examinations, as well as the Final examination fees.

There are six periods of examination annually, four in Edinburgh and two in Glasgow, and candidates may present themselves at either examining centre irrespectively of the place of the previous examination. The Registrar in Edinburgh is Mr. J. Robertson, solicitor, 54, George-square; and the Registrar in Glasgow, Mr. A. Duncan, LL.D., 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations.

Note.—In applying for copies of the Regulations students should state whether they commenced medical study before or after Jan. 1st, 1892, a warning which it is to be hoped has no longer much application.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians and the Royal College of Surgeons of Edinburgh grant honour diplomas which no longer give the right to practise professionally if held separately, and also grant their Single Licence to candidates already possessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship*.

Membership.—A candidate, who must be a Licentiate of the College of Physicians or a graduate of a British or Irish University and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine, such as general pathology, psychology, public health; obstetrics, tropical medicine, or medical jurisprudence. A candidate who for 40 years has been in the practise of his profession may be excused any or all of the examination. The fee for the Membership is £36 15*s*., 15 guineas of which will be returned to any successful candidate who was already a Licentiate of the College at the time of qualifying for the Membership.

Fellowship.—The Fellows are selected, save with rare exceptions, from the ranks of the *Members*. They must be 25 years of age. The fee is £64 18*s*.

The College grants its *Single Licence* on terms similar to those of the Royal College of Surgeons of Edinburgh, as mentioned in the next section.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The Royal College of Surgeons of Edinburgh grants a diploma of Fellowship after examination to the holders of the surgical degrees of diplomas of the recognised British examining bodies, as well as of the holders of the surgical degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire. The candidates for the examination must be 25 years of age and must have been engaged in practice for at least two years The examination is of a practical nature, partly written and partly *viva voce*, and includes surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject can also be taken, the range of these specialisms covering every branch of medicine. The fee to be paid on obtaining Fellowship is £45, £15 of which will be returned to those who already hold the Licentiateship of the College. *Three weeks'*

Only a few years ago he was limited to the medical treatises appearing in the British Isles, but now in addition he has the very large supply of works from the other side of the Atlantic, for several American publishing houses have established branches in this country from which they are putting out works of the highest order. From these three things—the large supply of text-books, their excellent and authoritative nature, and the addition of many valuable American works to our library—arises the impossibility of suggesting to the student what should and what should not be the book he ought to buy.

RECENT MEDICAL LITERATURE.

In drawing attention to some of the more interesting and important publications of the year we do not attempt in the course of a few brief remarks to furnish a substitute for detailed criticism. The books mentioned have all been noticed in our own columns and in those of our contemporaries during the past 12 months, and the reasons why we think it right to give them further mention appear in our reviews.

In Medicine and Pathology there have been reissues of several of the standard text-books, notably the second volume of the second edition of Dr. HOBART AMORY HARE'S *Text-book of Practice* (Henry Kimpton, 21s.); another work of American origin, *Modern Clinical Medicine*, by Dr. R. C. CABOT (Sidney Appleton, 21s.); and an excellent *Text-book on General and Special Pathology*, by Dr. R. T. HEWLETT (J. and A. Churchill, 10s. 6d.). The first volume of a new edition of Professor OSLER'S *System of Medicine* is published this month, Dr. T. MCCRAE, associate professor of medicine and clinical therapeutics at the Johns Hopkins University, being Professor OSLER'S collaborator. Other new books that may be recommended to the student in this section of his work are *Minor Maladies and their Treatment*, by Dr. LEONARD WILLIAMS (Baillière, Tindall, and Cox, 5s. net); *Physical Diagnosis*, by Dr. E. LE FEVRE (Hodder and Stoughton, 10s. net); *Medical Diagnosis*, by Dr. GRAHAM BROWN and Dr. W. T. RITCHIE (William Green and Sons. 8s. net); and *Chemical Pathology*, by H. GIDEON WELLS (W. B. Saunders and Co., 15s.). *Climatotherapy and Balneotherapy*, by Sir HERMANN WEBER and Dr. F. PARKES WEBER (Smith, Elder, and Co., 15s. net), has made its appearance in the third edition. Although this is not exactly a book for students, yet it is a valuable adjunct to the literature of medical treatment, and, as it is easy reading, we recommend the student to peruse it. Three interesting books dealing with the diseases of children appeared during the year. The first of these, *Functional Nervous Disorders in Childhood*, by Dr. L. GUTHRIE (Oxford Medical Manuals, Henry Frowde and Hodder and Stoughton, 7s. 6d.), is an extremely interesting work; the functional neuroses and psychoses of childhood have been all reviewed with extreme care. A second edition of Dr. H. KOPLIK'S well-known *Diseases of Infancy and of Childhood* (H. Kimpton, 25s.), and a work by Dr. A. C. COTTON on the *Medical Diseases of Infancy* (Lippincott, 15s.), will also be found of great interest. The fifth edition of Dr. H. LEWIS JONES'S *Medical Electricity* (H. K. Lewis, 12s. 6d.) has appeared, and a useful work has been written by Mr. HIGHAM COOPER on the *Use of X Rays in General Practice* (Baillière, Tindall, and Cox, 2s. 6d. net). Dr. HUGH WALSHAM'S *Roentgen Rays in the Diagnosis of Diseases of the Chest* (H. K. Lewis, 6s. net), can be thoroughly recommended.

No new work of first importance in General Surgery appeared during the year, though many interesting monographs on surgical topics have been written. The developments of surgery, no less than the merits of the accepted classics on the subject, make it appear unnecessary that for the present a new systematic work should be produced. The demand for new editions of three works on anæsthetics sufficiently shows that the dearth of surgical text-books does not necessarily mean any falling off in the amount of operative surgery performed. Dr. DUDLEY BUXTON'S work on *Anæsthetics* makes its appearance in a fourth edition (H. K. Lewis, 7s. 6d.) and Dr. FREDERIC HEWITT'S *Anæsthetics and their Administration* (Macmillan and Co., 15s.) in a third edition, while Dr. J. BLUMFELD'S much smaller *Manual on Anæsthetics* (Baillière, Tindall, and Cox, 2s. 6d. net) appears in a second edition.

Of the literature of Ophthalmological Surgery the principal contributions have been the third volume of Part I. of Mr. J. H. PARSONS'S *Pathology of the Eye* (Hodder and Stoughton, 15s. net) and the ninth edition of Sir H. R. SWANZY'S *Handbook of Diseases of the Eye* (H. K. Lewis, 12s. 6d.). Both these are absolutely first-class works indispensable to ophthalmologists. A useful book, entitled *Ophthalmic Operations*, has also been written by Mr. HAROLD GRIMSDALE and Mr. E. BREWERTON (Kegan Paul, Trench, Trübner, and Co., 12s. net).

Among text-books in Gynæcology and Midwifery the best new book of the year is Dr. T. W. EDEN'S *Manual of Midwifery* (J. and A. Churchill, 10s. 6d. net), in the review of which we were able to recommend it to students and practitioners alike as an excellent text-book.

The most important contribution to the literature of Public Health of the year was the addition to the *System of Hygiene* published under the editorship of the late Professor BROUARDEL and Dr. E. MOSNY (J. B. Baillière and Son, 9 francs). The last section to appear is the tenth, and deals with Naval Hygiene.

Of the three most important works on Psychiatry one only, the *Hygiene of the Mind* (Methuen and Co., 7s. 6d.), is by a British physician, Dr. T. S. CLOUSTON, and the work is more or less of a popular nature. The author has striven in every direction to be practical. Another valuable book is a *Text-book of Psychiatry for Physicians and Students* (Baillière, Tindall, and Cox, 21s. net), written by Dr. L. BIANCHI, professor of psychiatry of the University of Naples, and translated from the Italian by Dr. J. H. MACDONALD. The book exhibits a cosmopolitan acquaintance with the literature of the subject and is very well illustrated. The second edition of the English translation of Dr. EMIL KRAEPELIN'S *Lectures on Clinical Psychiatry* (Baillière, Tindall, and Cox, 10s. 6d.) also has made its appearance.

In the different departments ancillary to medicine many new editions of works which are of value to all students and teachers have made their appearance: for example, a new edition has appeared of Dr. E. H. STARLING'S *Elements of Human Physiology* (J. and A. Churchill, 12s. 6d. net), of Professor W. D. HALLIBURTON'S *Essentials of Chemical Physiology* (Longmans, Green, and Co., 4s. 6d. net), of Professor E. A. SCHÄFER'S *Essentials of Histology* (Longmans, Green, and Co., 10s. 6d.), and a ninth edition of *The Frog*, by Professor MARSHALL (David Nutt, 5s.). Sir ALMROTH E. WRIGHT has produced a *Handbook to the Microscope* (Constable and Co., 21s.) which explains to the student the principles of microscopy. The work is not an absolutely simple one, but those students who, not being satisfied with rule of thumb, are prepared to take the trouble to read Sir A. E. WRIGHT'S book will be amply repaid. Professor WERNER SPALTEHOLZ'S *Hand Atlas of Human Anatomy*, in three volumes (Lippincott, £2 2s.), is a valuable work for students and teachers.

SERIAL MEDICAL LITERATURE.

The student will find it of advantage to read medical journals and magazines occasionally. We do not suggest that he should do this in any systematic manner. The text-books that he must master are sufficiently numerous; some of the time, at any rate, that he can spare had better be spent in the pursuit of general literature. But he will often benefit by reading odd articles in current medical publications. Many of the official lectures at the Royal Colleges, for example, most of which are published at full length in our columns, form excellent epitomes of our knowledge of important subjects. The student who takes the trouble to compare his views, as derived from his manual and his practical experience, with the information given by these lectures, will be surprised at the gaps in his knowledge, but gratified to find that in the process of filling up these gaps he has mastered his subject.

THE INTERNATIONAL CONGRESS ON HYGIENE AND DEMOGRAPHY.—The senate of the city of Hamburg has invited the Fourteenth International Congress on Hygiene and Demography to visit the hygienic institutes of Hamburg. The excursion to Hamburg will take place after the closure of the Congress, provision having been made for 500 persons, ladies and gentlemen, to participate. The city of Hamburg is publishing a special volume to commemorate this visit and to serve at the same time as a guide to the institutes to be visited. An official reception will take place at the Hamburg Town-hall. A local committee is making arrangements for the reception of visitors. Lodgings at Hamburg will be procured on application to the Tourist Office of the Hamburg-Amerika Linie, 8, Unter den Linden, Berlin W. 64.

months; (*b*) Clinical Instruction in Ophthalmic and Aural Surgery for three months; (*c*) a Midwifery Hospital or Maternity, six months; (*d*) Vaccination; and (*e*) Clinical Instruction in Mental Diseases, one month; and (3) Courses of Instruction at a recognised medical school in (*a*) Medicine, six months; (*b*) Surgery, six months; (*c*) Operative Surgery, three months; and (*d*) Midwifery (including Diseases Peculiar to Women and to New-born Children), six months.

The subjects for the Fourth Professional Examination are the following:—(1) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (2) Surgery, including Operative Surgery and Ophthalmic Surgery; (3) Midwifery, including Diseases of Women and New-born Children and Vaccination. Every candidate shall produce evidence of having acted as medical clinical clerk and as surgical dresser. Candidates may present themselves for examination in *all* the subjects of the Final Examination at the *same* time or in certain groups of subjects. The fee for this examination is £6 6*s*. Further particulars can be obtained on application to Alfred Miller, Secretary of the Committee of Management, Royal College of Physicians, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing is exempted from the examination by printed questions.

Fees.—Fee for the Licence to practise Medicine, £15 15*s*. Fee for examination for the Licences in Medicine and Midwifery, if obtained within the interval of a month, £16 16*s*.—to be lodged in one sum. Any candidate who has been rejected at the examination for the Licence in Medicine loses this privilege and will be required to pay the full fee of five guineas for the Licence in Midwifery. Fee for special examination for the Licence to practise Medicine, £21. Fee for examination for the Licence to practise Midwifery, £5 5*s*. Fee for special examination for the Licence to practise Midwifery, £10 10*s*. The examinations for these Licences are held in the week following the first Friday in February, May, and November.

The Membership.—Examinations for Membership are held in January, April, July, and October. The fee for the examination is £21 to Licentiates of the College, or £36 15*s*. to non-Licentiates. Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Licence in Surgery.—Candidates who hold registrable surgical diplomas (including the Licence of the Apothecaries' Companies of London and Dublin granted since October, 1886) are admitted to examination without further evidence of study. Candidates who hold medical qualifications only (including the L.S.A. granted before October, 1886) will be required to produce certificates of two courses of lectures in Anatomy and Dissections, one course of Practical Histology, one course of lectures in Surgery, and one course of Operative Surgery. Candidates are examined in Surgery, Clinical Surgery, Operative Surgery on the subject, Surgical Appliances, and Ophthalmic Surgery. The examination is partly written, partly *vivâ voce*, and partly practical. The fee is £26 5*s*., of which £5 5*s*. is retained by the College in the case of unsuccessful candidates.

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification. Candidates must produce evidence of (*a*) attendance on a course of lectures on Midwifery and Diseases of Women and Children in some school recognised by the Council; (*b*) attendance on six months' practice in connexion with a recognised lying-in hospital or dispensary for lying-in women and children; and (*c*) of having conducted at least 30 labour cases. The fee for the examination is £15 15*s*., of which £5 5*s*. is retained by the College in case the candidate is unsuccessful.

Fellowship Examinations.—A candidate for the Fellowship shall make application to the President and Council to be admitted to examination and if the Council decide to entertain that application it shall lie on the table for at least a fortnight for consideration before it is put to the Council for approval. All the required evidences of study or qualification, fees, and testimonials as to character must be submitted previously to the application being considered, and the candidate shall then, if approved by the Council, be admitted to the next Sessional examination or to a special examination if granted by the Council, at such date as the President may fix. In order that these regulations may be carried out candidates are required to lodge their applications complete with the Registrar at least one month before the date of examination. Sessional Fellowship examinations commence, so far as arrangements permit, on the third Mondays in February, May, and November. Special examinations may be granted at other times by the Council if they see fit, on sufficient cause being shown, except during the months of August and September. Candidates for the Fellowship examination are divided into two Grades: I., Licentiates or Graduates in Surgery of less than 10 years' standing; II., Licentiates or Graduates in Surgery of more than 10 years' standing. Students not either Licentiates or Graduates in Surgery are permitted to present themselves for the *Primary* examination under Grade I.

Grade I.—Candidates are required to pass two examinations — Primary and Final. Candidates may present themselves for the Final examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology.

The subjects for the Final examination are (*a*) Surgery, including Clinical and Operative Surgery; and (*b*) Surgical Pathology.

Grade II.[1]—The subjects for examination are (*a*) Surgical Anatomy; (*b*) Surgery, including Clinical and Operative Surgery; and (*c*) Surgical Pathology.

Fees.—Grade I.:—*For Licentiates of the College:* for Primary examination, £15 15*s*.; for Final examination, £10 10*s*. *For Licentiates in Surgery of other licensing bodies:* for Primary examination, £26 5*s*.; for Final examination, £15 15*s*. *For Students of the College:* for Primary examination, £5 5*s*.; for Final examination, £21. For Students of other licensing bodies: for Primary examination, £10 10*s*.; for Final examination, £31 10*s*. Grade II.:—Licentiates of the College, £26 5*s*.; Licentiates in Surgery of other licensing bodies, £42; extra fee for Special examination, £10 10*s*.

In case of rejection £10 10*s*., in addition to the special fee, if such has been paid, is retained by the College and is not allowed in the fees of re-examination.

A rejected candidate will not be again admitted to examination until after a period of three months.

Further particulars can be obtained from the Registrar of the College, Stephen's-green, West Dublin.

SOCIETY OF APOTHECARIES OF LONDON.

There are two examinations—Primary and Final. The Final examination is divided into Section I. and Section II. The Primary examination is held quarterly. Final examinations are held monthly. No examinations are held in the month of September.

The *Primary examination* consists of two parts. Part I. Elementary Biology; Chemistry, Chemical Physics, including the Elementary Mechanics of Solids and Fluids, Heat, Light, and Electricity; Practical Chemistry; and Materia Medica and Pharmacy. A synopsis indicating the range of the subjects in the examination will be sent with the regulations on application. Evidence of instruction in these subjects must be produced prior to examination. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects

---

[1] On and after Jan. 1st, 1910, all Examinations for the Fellowship will be conducted under the scheme now known as Grade I. No candidate after the above date will, in any circumstances, be admitted to examination for the Fellowship of this College under the Scheme now known as Grade II., which will then cease to be used.

The General Medical Council is in no way a medical protection society or a medical defence union. It is not a professional union or a guild charged with looking after the interests of the medical profession after the manner of the old trades guilds, except in so far as it is concerned with the education of medical students. It has no powers over any member of the medical profession except to remove the name of any offending member from the roll of the profession or Medical Register. It cannot take away any degree, or diploma, or licence, and even if a practitioner is struck off the Medical Register there is nothing in the existing state of the law to prevent such practitioner continuing to practise, provided that he does not use any name or title implying that he is registered. Practitioners may be removed from the Medical Register (1) if convicted of felony or misdemeanour in England, or in Ireland, or in Scotland of any crime or offence, and (2) on being adjudged by the General Medical Council to have been guilty of "infamous conduct in a professional respect."

The General Medical Council is, we repeat, primarily a body charged with looking after medical education; it is but little concerned with medical politics and, as a matter of fact, the time of the Council is almost entirely taken up with considering educational and registration matters, the latter including the penal cases of removal from the Register. The Council at present consists of 34 members, of whom, as will be seen by the annexed list, all but 10 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and five others are elected by the members of the medical profession as Direct Representatives.

President of the General Council.—Dr. Donald MacAlister. Members of the General Council.—Dr. Norman Moore, chosen by the Royal College of Physicians of London; Mr. Henry Morris, Royal College of Surgeons of England; Sir Hugh Reeve Beevor, Bart., Apothecaries' Society of London; Mr. Arthur Thomson, M.B., University of Oxford; Dr. Donald MacAlister, University of Cambridge; Sir George Hare Philipson, University of Durham; Dr. Philip Henry Pye-Smith, University of London; Mr. Alfred Harry Young, M.B., Victoria University of Manchester; Dr. Robert Saundby, University of Birmingham; Dr. Richard Caton, University of Liverpool; Dr. Alfred George Barrs, University of Leeds; and Dr. William Tusting Cocking, University of Sheffield. Sir John Batty Tuke, M.P., chosen by the Royal College of Physicians of Edinburgh; Dr. James William Beeman Hodsdon, Royal College of Surgeons of Edinburgh; Dr. John Lindsay Steven, Faculty of Physicians and Surgeons of Glasgow; Sir Thomas Richard Fraser, M.D., University of Edinburgh; Sir Thomas McCall Anderson, University of Glasgow; Dr. David White Finlay, University of Aberdeen; and Dr. John Yule Mackay, University of St. Andrews. Sir John William Moore chosen by the Royal College of Physicians of Ireland; Sir Thomas Myles, Royal College of Surgeons in Ireland; Dr. Francis George Adye-Curran, Apothecaries' Hall of Ireland; Sir Charles Ball, University of Dublin; and Sir Christopher John Nixon, Bart., Royal University of Ireland. Nominated by His Majesty, with the advice of his Privy Council: Mr. Charles Sissmore Tomes, Mr. William Henry Power, C.B., Sir John Williams, Bart., K.C.V.O., Dr. David Caldwell McVail, and Dr. James Little. Elected as Direct Representatives: Dr. Langley Browne, Dr. H. A. Latimer, Dr. L. A. McManus, Dr. Norman Walker, Dr. William Bruce, and Dr. Leonard Kidd. Treasurers of the General Council: Dr. Philip Henry Pye-Smith and Mr. Charles Sissmore Tomes.

THE EDUCATIONAL CURRICULUM.

Professional Education.—The course of professional study after registration shall occupy at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

Registration and Preliminary Examination of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—

Every medical student shall be registered in the manner prescribed by the General Medical Council. The registration of medical students shall be placed under the charge of the branch registrars. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has attained the age of 16 years, and has commenced medical study. The branch registrar shall enter the applicant's name and other particulars in the Students' Register and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than 15 days before the date of registration. In addition to the universities and schools of medicine there are many institutions where medical study may be commenced. Applications for special exceptions are dealt with by the Students' Registration Committee, which reports all such cases to the Council.

The Preliminary Examination in General Education, required to be passed previously to registration as a medical student, is as follows:—

1. English language, including grammar and composition. 2. Latin, including grammar, translation from unprescribed Latin books, and translation of English passages into Latin. 3. Mathematics, comprising (*a*) arithmetic, (*b*) algebra, including easy quadratic equations, and (*c*) geometry, the subject matter of Euclid, Books I., II., and III., with easy deductions. 4. One of the following subjects: (*a*) Greek, (*b*) a modern language.

In many cases the Council will not accept certificates of pass in Preliminary Examination in General Education unless the whole of the subjects included in the Preliminary Examination required by the Council for Registration of Students of medicine have been passed at the same time.

A degree in Arts of any university of the United Kingdom or of the colonies or a certificate of having passed the final examination for a degree in Arts or Science of any university in the United Kingdom is considered a sufficient testimonial of proficiency.

H. E. Allen, LL.B., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W.—James Robertson, Registrar of the Branch Council for Scotland, 54, George-square, Edinburgh.—Richard J. E. Roe, Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

THE EXAMINING BODIES.

The following is a list of Examining Bodies whose examinations in general education are recognised by the General Medical Council as qualifying for registration as a medical or dental student.

I.—*Universities in the United Kingdom.*

University of Oxford.—Junior Local Examinations. Senior Local Examinations. Higher Local Examinations. Responsions. Moderations.

University of Cambridge.—Junior Local Examinations. Senior Local Examinations. Higher Local Examinations. Previous Examination. General Examination.

University of Durham.—Matriculation Examination for Science, Letters, and Music. Senior Local Examinations.

University of London.—Matriculation Examination.

Victoria University of Manchester.—Matriculation Examination.

University of Birmingham.—Matriculation Examination.

University of Liverpool.—Matriculation Examination.

University of Leeds.—Matriculation Examination.

University of Wales.—Matriculation Examination.

University of Edinburgh.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery.

University of Aberdeen.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery.

University of Glasgow.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery.

University of St. Andrews.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery. Final Examination for the diploma of L.L.A.

University of Dublin.—Public Entrance Examination. Examination for the first, second, third, or fourth year in Arts.
